

# Towards MKM in the Large: Modular Representation and Scalable Software Architecture

Michael Kohlhase, Florian Rabe, Vyacheslav Zholudev

Jacobs University Bremen

# Motivation

- ▶ Focus: computer-supported deduction, computation, representation of mathematical knowledge
- ▶ Well-studied in the small – but serious applications require large scale formalized mathematics, verification, ...  
distributed, collaborative, web-based
- ▶ Problems:
  - ▶ systems focus on in-memory processing
  - ▶ lack of formalized/annotated content
  - ▶ integration, extension of formal systems hard
- ▶ Here: infrastructure to separate the concerns
  - ▶ small scale systems when possible
  - ▶ dedicated systems for large scale aspects
  - ▶ flexible/transparent connection between them

# Background

- ▶ Long term goal:
  - ▶ comprehensive framework to represent, integrate, translate, reason about logics
  - ▶ apply to all commonly used logics, generate large content base
  - ▶ cover model and proof theory
  - ▶ provide tool support: validation, browsing, editing, storage, ...
  - ▶ digital library of logics
- ▶ Observation: objectives highly inter-dependent, e.g.,
  - ▶ evaluation of framework requires case studies
  - ▶ case studies only feasible with strong module system, editor, etc.

# Background

- ▶ Long term goal:
  - ▶ comprehensive framework to represent, integrate, translate, reason about logics
  - ▶ apply to all commonly used logics, generate large content base
  - ▶ cover model and proof theory
  - ▶ provide tool support: validation, browsing, editing, storage, ...
  - ▶ digital library of logics
- ▶ Observation: objectives highly inter-dependent, e.g.,
  - ▶ evaluation of framework requires case studies
  - ▶ case studies only feasible with strong module system, editor, etc.
  - ▶ therefore: make them generic  
become separate research projects
- ▶ Slogan: If you have 8 hours to chop down a tree, spend 6 sharpening your ax.  
most of the sharpening done now

# Overview

- ▶ MMT: scalable representation language  
modular, foundation-independent, web-standard-compliant  
interface layer between formal and web systems
- ▶ TNTBase: scalable XML+SVN database [Balisage 2009]  
plugin for server-side MMT processing
- ▶ JOBAD: Javascript library for active documents [MKM 2009]  
plugin for client side MMT processing
- ▶ LF/Twelf: type theoretical logical framework  
extended for MMT generation [LFMTP 2009]
- ▶ MKMIDE: generic editing support [MKM 2010]  
to do: plugin for MMT/LF

# Representation language (MMT)

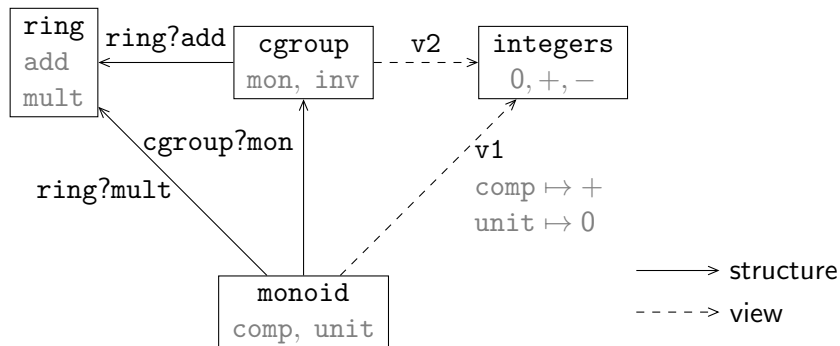

- ▶ MMT = module system for mathematical theories
- ▶ Formal syntax and semantics
  - ▶ needed for mathematical interface language
  - ▶ but how to avoid foundational commitment?
- ▶ Foundation-independence
  - ▶ identify aspects of underlying language that are necessary for large scale processing
  - ▶ formalize exactly those, be parametric in the rest
  - ▶ observation: most large scale operations need the same aspects
- ▶ Module system
  - ▶ preserve mathematical structure wherever possible
  - ▶ formal semantics for modularity
- ▶ Web-scalable
  - ▶ build on XML, OpenMath, OMDoc
  - ▶ URI-based logical identifiers for all declarations

# Module System

- ▶ Central notion: theory graph with theories as nodes and theory morphisms as edges
- ▶ Two kinds of theory morphisms
  - ▶ structures instantiate theories in a new context (also called: definitional link, import)  
import of theory  $S$  into theory  $T$  induces theory morphism  $S \rightarrow T$
  - ▶ views translate between existing theories (also called: postulated link, theorem link)

# Example

v2  
 $\left\{ \begin{array}{l} \text{mon/comp} \mapsto + \\ \text{mon/unit} \mapsto 0 \end{array} \right\}$  or  $\text{mon} \mapsto \text{v1}$   
 $\text{inv} \mapsto -$

## Example (2)

- ▶ Logics and foundations represented as theories  
subject to the same module system
- ▶ Meta-relation between theories  
special case of inclusion
- ▶ Semantics of logics represented as theory morphisms into the foundation, e.g., `folsem`
- ▶ Similarly models  $M$  represented as theory morphisms

## Module System: Case Studies

- ▶ Created using MMT instantiation of logical framework LF/Twelf
- ▶ Fully modular, highly interrelated
- ▶ Foundations: ZFC, Isabelle/HOL, Mizar
- ▶ Type theories:  $\lambda$ -cube
- ▶ Logics: FOL, SFOL, HOL, ML, DL, ...
- ▶ Logic translations: SFOL-FOL, FOL-SFOL, FOL-HOL, PL-IPL, ML-FOL, ...
- ▶ Algebra: 180 lines structured (1800 lines flattened)
- ▶ Lattices: 310 lines structured (3500 lines flattened)
- ▶ 100 files, 200 theories, 50 views, 5 authors

# Web-Scalability

- ▶ Concrete syntax based on XML, OPENMATH, OMDoc
- ▶ Crucial: good data structure for identifiers
  - ▶ all theories, views, constants, structures (including imported ones) addressable by URIs
  - ▶ abstract from physical locations
  - ▶ implementation needed everywhere: deduction system (SML, Haskell), database (XQuery), browser (Javascript), editor (Bean Shell), etc.
- ▶ Intertwined with language design!
  - ▶ understanding the identifiers means understanding the module system
  - ▶ e.g., MMT inference system based on ADD, GET requests

## Example

namespace:  $NS = \text{http://cds.omdoc.org/algebra.omdoc}$

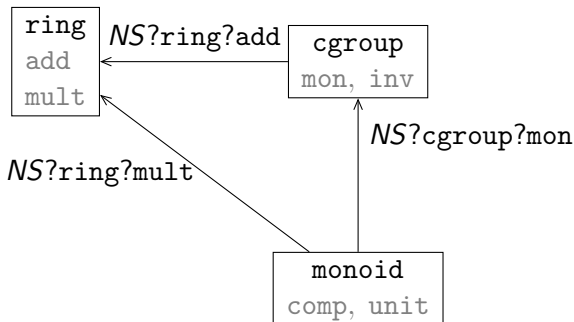

theory:  $NS?monoid$

symbol:  $NS?monoid?unit$

imported symbols:

$NS?ring?mult/unit$

$NS?ring?add/mon/unit$

# MMT Implementation

- ▶ Based on Scala good language and Java-compatible
- ▶ Run as API, scriptable shell, local server, web server  
use online or offline
- ▶ Structural validation: stronger than XML schema but still  
foundation-independent incremental
- ▶ RDF extraction for indexing invertible
- ▶ Catalog to translate URIs into URLs, hides physical locations
- ▶ Query engine for MMT-URIs and MMT-RDF
- ▶ Notation language for flexible rendering

## Database: TNTBase

- ▶ Combines Berkeley DB XML and SVN backend storage
- ▶ Versioned XQueryUpdate
- ▶ RESTful interface
- ▶ Document format-specific abstraction layer
  - pre/post-commit hooks, XQuery, Java
- ▶ Editable virtual documents corresponding to views in relational databases

# MMT in TNTBase

- ▶ MMT plugin for TNTBase: MMT-aware querying, searching, indexing
- ▶ When committing: TNTBase calls MMT-API to
  - ▶ incrementally validate added/changed documents
  - ▶ compute and index RDF presentation
- ▶ When querying: XQuery functions provided to
  - ▶ dereference MMT-URIs
  - ▶ query indexed RDF
  - ▶ compute dependency closure

## Example

- ▶ Render the theory *TypedZFC*
  - ▶ ZFC set theory + various type theories + views establishing typed reasoning in ZFC
  - ▶ depends on about 100 other modules
  - ▶ no need to retrieve them all but they may contain notations
- ▶ Without TNTBase: recursively retrieve, parse, scan all files, get notations slow even when all files are local
- ▶ With TNTBase: a single XQuery almost immediate

# Conclusion

- ▶ MMT representation language
  - ▶ modular, foundation-independent, web-scalable
  - ▶ interface language between small scale formal systems and large scale web systems
  - ▶ to become part of OMDoc 2
- ▶ MMT reference implementation
  - ▶ incremental, structural validation
  - ▶ flexible integration as subsidiary service
  - ▶ flexible integration with storage backends
- ▶ TNTBase database
  - ▶ SVN, XML, XPath, XQueryUpdate
  - ▶ stable and released
  - ▶ plugin for MMT-aware indexing, querying, search
- ▶ Integration with editors, formal systems, web servers, web browsers
