

Artificial Intelligence 1
Winter Semester 2023/24
– Lecture Notes –

Prof. Dr. Michael Kohlhase
Professur für Wissensrepräsentation und -verarbeitung
Informatik, FAU Erlangen-Nürnberg
Michael.Kohlhase@FAU.de

2024-02-08

0.1 Preface

0.1.1 Course Concept

Objective: The course aims at giving students a solid (and often somewhat theoretically oriented) foundation of the basic concepts and practices of artificial intelligence. The course will predominantly cover [symbolic AI](#) – also sometimes called “good old-fashioned AI (GofAI)” – in the first semester and offers the very foundations of [statistical approaches](#) in the second. Indeed, a full account [sub symbolic](#), [machine learning](#) based AI deserves its own specialization courses and needs much more [mathematical](#) prerequisites than we can assume in this course.

Context: The course “Artificial Intelligence” (AI 1 & 2) at FAU Erlangen is a two-semester course in the “Wahlpflichtbereich” (specialization phase) in semesters 5/6 of the Bachelor program “Computer Science” at FAU Erlangen. It is also available as a (somewhat remedial) course in the “Vertiefungsmodul Künstliche Intelligenz” in the Computer Science Master’s program.

Prerequisites: AI-1 & 2 builds on the mandatory courses in the FAU Bachelor’s program, in particular the course “Grundlagen der Logik in der Informatik” [Glo], which already covers a lot of the materials usually presented in the “knowledge and reasoning” part of an introductory AI course. The AI 1& 2 course also minimizes overlap with the course.

The course is relatively elementary, we expect that any student who attended the mandatory CS courses at FAU Erlangen can follow it.

Open to external students:

Other Bachelor programs are increasingly co-opting the course as specialization option. There is no inherent restriction to [computer science](#) students in this course. Students with other study biographies – e.g. students from other Bachelor programs our external Master’s students should be able to pick up the prerequisites when needed.

0.1.2 Course Contents

Goal: To give students a solid foundation of the basic concepts and practices of the field of [Artificial Intelligence](#). The course will be based on Russell/Norvig’s book “*Artificial Intelligence: A modern Approach*” [RN09]

Artificial Intelligence I (the first semester): introduces AI as an area of study, discusses “rational agents” as a unifying conceptual paradigm for AI and covers problem solving, search, constraint propagation, logic, knowledge representation, and planning.

Artificial Intelligence II (the second semester): is more oriented towards exposing students to the basics of statistically based AI: We start out with reasoning under [uncertainty](#), setting the foundation with Bayesian Networks and extending this to rational decision theory. Building on this we cover the basics of [machine learning](#).

0.1.3 This Document

Format: The document mixes the slides presented in class with comments of the instructor to give students a more complete background reference.

Caveat: This document is made available for the students of this course only. It is still very much a draft and will develop over the course of the current course and in coming academic years. **Licensing:** This document is licensed under a [Creative Commons license](#) that [requires attribution](#), [allows commercial use](#), and [allows derivative works](#) as long as [these are licensed under the same license](#).

Knowledge Representation Experiment: This document is also an experiment in knowledge representation. Under the hood, it uses the [\$\LaTeX\$](#) package [Koh08; sTeX], a [\$\TeX\$ / \$\LaTeX\$](#) extension for semantic markup, which allows to export the contents into [active documents](#) that adapt to the reader and can be instrumented with services based on the explicitly represented meaning of the documents.

0.1.4 Acknowledgments

Materials: Most of the materials in this course is based on Russel/Norvik’s book “Artificial Intelligence — A Modern Approach” (AIMA [RN95]). Even the slides are based on a L^AT_EX-based slide set, but heavily edited. The section on search algorithms is based on materials obtained from Bernhard Beckert (then Uni Koblenz), which is in turn based on AIMA. Some extensions have been inspired by an AI course by Jörg Hoffmann and Wolfgang Wahlster at Saarland University in 2016. Finally Dennis Müller suggested and supplied some extensions on AGI. Florian Rabe, Max Rapp and Katja Berčič have carefully re-read the text and pointed out problems.

All course materials have been restructured and semantically annotated in the S^TE_X format, so that we can base additional semantic services on them.

AI Students: The following students have submitted corrections and suggestions to this and earlier versions of the notes: Rares Ambrus, Ioan Sucan, Yashodan Nevatia, Dennis Müller, Simon Rainer, Demian Vöhringer, Lorenz Gorse, Philipp Reger, Benedikt Lorch, Maximilian Lösch, Luca Reeb, Marius Frinken, Peter Eichinger, Oskar Herrmann, Daniel Höfer, Stephan Matthejat, Matthias Sonntag, Jan Urfei, Tanja Würsching, Adrian Kretschmer, Tobias Schmidt, Maxim Onciul, Armin Roth, Liam Corona, Tobias Völk, Lena Voigt, Yinan Shao, Michael Girstl, Matthias Vietz, Anatoliy Cherepantsev, Stefan Musevski, Matthias Lobenhofer, Philipp Kaludercic, Diwarkara Reddy, Martin Helmke, Stefan Müller, Dominik Mehlich, Paul Martini, Vishwang Dave, Arthur Miehlisch, Christian Schabesberger, Vishaal Saravanan, Simon Heilig, Michelle Fribrance, Wenwen Wang, Xinyuan Tu, Lobna Eldeeb.

0.1.5 Recorded Syllabus

The recorded syllabus – a record the progress of the course in the academic year 2023/24– is in the course page in the ALEA system at <https://courses.voll-ki.fau.de/course-home/ai-1>. The table of contents in the AI-1 notes at <https://courses.voll-ki.fau.de> indicates the material covered to date in yellow.

The recorded syllabus of AI-2 can be found at <https://courses.voll-ki.fau.de/course-home/ai-2>. For the topics planned for this course, see subsection 0.1.2.

Chapter 1

Preliminaries

In this chapter, we want to get all the organizational matters out of the way, so that we can get into the discussion of [artificial intelligence](#) content unencumbered. We will talk about the necessary administrative details, go into how students can get most out of the course, talk about where the various resources provided with the course can be found, and finally introduce the [ALEA](#) system, an experimental – using [AI](#) methods – learning support system for the [AI](#) course.

1.1 Administrative Ground Rules

We will now go through the ground rules for the course. This is a kind of a social contract between the instructor and the students. Both have to keep their side of the deal to make learning as [efficient](#) and painless as possible.

Prerequisites for AI-1

- ▷ **Content Prerequisites:** The mandatory courses in CS@FAU; Sem 1-4, in particular:
 - ▷ Course “Algorithmen und Datenstrukturen”. ([Algorithms & Data Structures](#))
 - ▷ Course “Grundlagen der Logik in der Informatik” (GLOIN). ([Logic in CS](#))
 - ▷ Course “Berechenbarkeit und Formale Sprachen”. ([Theoretical CS](#))
- ▷ **Skillset Prerequisite:** Coping with [mathematical](#) formulation of the structures
 - ▷ [Mathematics](#) is the language of science ([in particular computer science](#))
 - ▷ It allows us to be very precise about what we mean. ([good for you](#))
- ▷ **Intuition:** ([take them with a kilo of salt](#))
 - ▷ This is what I assume you know! ([I have to assume something](#))
 - ▷ In most cases, the dependency on these is partial and “in spirit”.
 - ▷ If you have not taken these (or do not remember), read up on them as needed!
- ▷ **Real Prerequisites:** Motivation, interest, curiosity, hard work. ([AI-1 is non-trivial](#))
- ▷ You can do this course if you want! ([and I hope you are successful](#))

Now we come to a topic that is always interesting to the students: the grading scheme.

Assessment, Grades

- ▷ **Overall (Module) Grade:**
 - ▷ Grade via the exam (Klausur) \leadsto 100% of the grade.
 - ▷ Up to 10% bonus on-top for an exam with $\geq 50\%$ points. ($\leq 50\% \leadsto$ no bonus)
 - ▷ Bonus points $\hat{=}$ percentage sum of the best 10 tuesday quizzes divided by 100.
- ▷ **Exam:** 90 minutes exam conducted in presence on paper (\sim April 1. 2024)
- ▷ **Retake Exam:** 90 min exam six months later (\sim October 1. 2024)
- ▷ **⚠** You have to register for exams in campo in the first month of classes.
- ▷ **Note:** You can de-register from an exam on campo up to three working days before.
- ▷ **Tuesday Quizzes:** Every tuesday we start the lecture with a 10 min online quiz – the tuesday quiz – about the material from the previous week. (starts in week 2)

Tuesday Quizzes

- ▷ **Tuesday Quizzes:** Every tuesday we start the lecture with a 10 min online quiz – the tuesday quiz – about the material from the previous week. (starts in week 2)
- ▷ **Motivations:** We do this to
 - ▷ keep you prepared and working continuously. (primary)
 - ▷ update the ALEA learner model (fringe benefit)
- ▷ The tuesday quiz will be given in the ALEA system
 - ▷ <https://courses.voll-ki.fau.de/quiz-dash/ai-1>
 - ▷ You have to be logged into ALEA!
 - ▷ You can take the quiz on your laptop or phone, ...
 - ▷ ... in the lecture or at home ...
 - ▷ ... via WLAN or 4G Network. (do not overload)
 - ▷ Quizzes will only be available 16:15-16:25!

Tomorrow: Pretest

- ▷  Tomorrow we will try out the [tuesday quiz](#) infrastructure with a [pretest](#)!
 - ▷ **Presence:** bring your laptop or cellphone.
 - ▷ **Online:** you can and should take the [pretest](#) as well.
 - ▷ Have a recent [firefox](#) or [chrome](#) ([chrome: \$\geq\$ March 2023](#))
 - ▷ Make sure that you are logged into [ALEA](#) ([via FAU IDM; see below](#))
- ▷ **Definition 1.1.1.** A [pretest](#) is an [assessment](#) for evaluating the preparedness of [learners](#) for further studies.
- ▷ **Concretely:** This [pretest](#)
 - ▷ establishes a baseline for the [competency](#) expectations in AI-1 and
 - ▷ tests the [ALEA](#) quiz infrastructure for the [tuesday quizzes](#).
- ▷ Participation in this test is optional; it will not influence your grades in any way.
- ▷ The test covers the prerequisites of AI-1 and some of the material that may have been covered in other courses.
- ▷ The test will be also used to refine the [ALEA learner model](#), which may make learning experience in [ALEA](#) better. ([see below](#))

Due to the current [AI](#) hype, the course Artificial Intelligence is very popular and thus many degree programs at FAU have adopted it for their curricula. Sometimes the course setup that fits for the [CS](#) program does not fit the other's very well, therefore there are some special conditions. I want to state here.

Special Admin Conditions

- ▷ Some degree programs do not “import” the course Artificial Intelligence, and thus you may not be able to register for the exam via <https://campus.fau.de>.
 - ▷ Just send me an e-mail and come to the exam, we will issue a “Schein”.
 - ▷ Tell your program coordinator about AI-1/2 so that they remedy this situation
- ▷ In “Wirtschafts-Informatik” you can only take AI-1 and AI-2 together in the “Wahlpflichtbereich”.
 - ▷ ECTS credits need to be divisible by five $\Leftarrow 7.5 + 7.5 = 15$.

I can only warn of what I am aware, so if your degree program lets you jump through extra hoops, please tell me and then I can mention them here.

1.2 Getting Most out of AI-1

In this section we will discuss a couple of measures that students may want to consider to get most out of the AI-1 course.

None of them – homeworks, tutorials, study groups, and attendance – are mandatory, but most of them are very clearly correlated with success (i.e. passing the exam and getting a good grade).

AI-1 Homework Assignments

- ▷ **Homework Assignments:** Small individual problem/*programming*/proof task
 - ▷ but take time to solve (at least read them directly \leadsto questions)
- ▷  **Homeworks** give no bonus points, but without trying you are unlikely to pass the exam.
- ▷ **Homework/Tutorial Discipline:**
 - ▷ **Start early!** (many assignments need more than one evening's work)
 - ▷ Don't start by sitting at a blank screen (talking & study group help)
 - ▷ Humans will be trying to understand the text/code/math when grading it.
 - ▷ **Go to the tutorials, discuss with your TA!** (they are there for you!)
- ▷  We will not be able to grade all homework assignments!
- ▷ **Graded Assignments:** To keep things running smoothly
 - ▷ **Homeworks** will be posted on StudOn.
 - ▷ Sign up for AI-1 under <https://www.studon.fau.de/crs4622069.html>.
 - ▷ **Homeworks** are handed in electronically there. (plain text, program files, PDF)
 - ▷ Do not sign up for the “AI-2 Übungen” on StudOn (we do not use them)
- ▷ **Ungraded Assignments:** Are peer-feedbacked in **ALEA** (see below)

It is very well-established experience that without doing the **homework assignments** (or something similar) on your own, you will not master the concepts, you will not even be able to ask sensible questions, and take very little home from the course. Just sitting in the course and nodding is not enough! If you have questions please make sure you discuss them with the instructor, the teaching assistants, or your fellow students. There are three sensible venues for such discussions: online in the lecture, in the tutorials, which we discuss now, or in the course forum – see below. Finally, it is always a very good idea to form study groups with your friends.

Tutorials for Artificial Intelligence 1

- ▷ **Approach:** Weekly tutorials and homework assignments (first one in week two)
- ▷ **Goal 1:** Reinforce what was taught in class. (you need practice)
- ▷ **Goal 2:** Allow you to ask any question you have in a protected environment.

- ▷ **Instructor/Lead TA:** Florian Rabe (KWARC Postdoc)
 - ▷ Room: 11.137 @ Händler building, florian.rabe@fau.de
- ▷ **Tutorials:** One each taught by Florian Rabe (lead); Mahdi Mantash, Robert Kurin, Florian Guthmann.
- ▷ **Life-saving Advice:** Go to your tutorial, and prepare for it by having looked at the slides and the homework assignments!
- ▷ **Caveat:** We cannot grade all submissions with 5 TAs and ~1000 students.
- ▷ **Also:** Group submission has not worked well in the past! (too many freeloaders)

Collaboration

- ▷ **Definition 1.2.1.** **Collaboration** (or **cooperation**) is the process of groups of agents working or acting together for common, mutual, or some underlying benefit, as opposed to working in **competition** for selfish benefit. In a **collaboration**, every agent contributes to the common goal.
- ▷ In learning situations, the benefit is “better learning outcomes”.
- ▷ **Observation:** In **collaborative** learning, the overall result can be significantly better than in **competitive** learning.
- ▷ **Good Practice:** Form **study groups**. (long- or short-term)
 - ▷ ⚠ those learners who work most, learn most
 - ▷ ⚠ freeloaders – individuals who only watch – learn very little!
- ▷ It is OK to collaborate on **homework assignments** in AI-1! (no bonus points)
- ▷ Choose your **study group** well (We will (eventually) help via ALeA)

What I am going to go into next is – or should be – obvious, but there is an important point I want to make.

Do I need to attend the lectures

- ▷ Attendance is not mandatory for the AI-1 lecture
 - ▷ There are two ways of learning AI-1: (both are OK, your mileage may vary)
 - ▷ Approach **B**: Read a **Book**
 - ▷ Approach **I**: come to the lectures, be **involved**, interrupt me whenever you have a question.
- The only advantage of **I** over **B** is that books do not answer questions (yet! ↔ we are working on this in AI research)

- ▷ Approach **S**: come to the lectures and **sleep does not work!**
- ▷ **I really mean it:** If you come to class, be involved, ask questions, challenge me with comments, tell me about errors, ...
 - ▷ I would much rather have a lively discussion than get through all the slides
 - ▷ You learn more, I have more fun (Approach B serves as a backup)
 - ▷ You may have to change your habits, overcome shyness, ... (please do!)
- ▷ This is what I get paid for, and I am more expensive than most books (get your money's worth)

1.3 Learning Resources for AI-1

But what if you are not in a lecture or tutorial and want to find out more about the AI-1 topics?

Textbook, Handouts and Information, Forums, Videos

- ▷ **Textbook:** *Russel/Norvig: Artificial Intelligence, A modern Approach* [RN09].
 - ▷ basically “broad but somewhat shallow”
 - ▷ great to get intuitions on the basics of AI

Make sure that you read the **edition ≥ 3** \leftrightarrow vastly improved over ≤ 2 .
- ▷ **Course notes:** will be posted at <http://kwarc.info/teaching/AI/notes.pdf>
 - ▷ more detailed than [RN09] in some areas
 - ▷ I mostly prepare them as we go along (semantically preloaded \rightsquigarrow research resource)
 - ▷ please e-mail me any errors/shortcomings you notice. (improve for the group)
- ▷ **StudOn Forum:** <https://www.studon.fau.de/crs4622069.html> for
 - ▷ announcements, homeworks (my view on the forum)
 - ▷ questions, discussion among your fellow students (your forum too, use it!)
- ▷ **Course Videos:** AI-1 will be streamed/recorded at <https://fau.tv/course/id/3595>
 - ▷ **Organized:** Video course nuggets are available at <https://fau.tv/course/id/1690> (short; organized by topic)
 - ▷ **Backup:** The lectures from WS 2016/17 to SS 2018 have been recorded (in English and German), see <https://www.fau.tv/search/term.html?q=Kohlhase>
- ▷ **Do not let the videos mislead you:** Coming to class is highly correlated with passing the course!

FAU has issued a very insightful guide on using lecture recordings. It is a good idea to heed these

recommendations, even if they seem annoying at first.

Practical recommendations on Lecture Resources

▷ Excellent Guide: [Nor+18a] (german Version at [Nor+18b])

-  Attend lectures.
-  Take notes.
-  Be specific.
-  Catch up.
-  Ask for help.
-  Don't cut corners.

Michael Kohlhase: Artificial Intelligence 1

11

2024-02-08

1.4 AI-Supported Learning

In this section we introduce the [ALEA](#) (Adaptive Learning Assistant) system, a [learning support system](#) we have developed using [symbolic AI](#) methods – the stuff we learn about in AI-1 – and which we will use to support students in the course. As such [ALEA](#) does double duty in this course it supports learning activities and serves as a showcase, what [symbolic AI](#) methods can do in an important application.

ALEA: Adaptive Learning Assistant

- ▷ **Idea:** Use [AI](#) methods to help teach/learn [AI](#) (AI4AI)
- ▷ **Concretely:** Provide [HTML](#) versions of the AI-1 slides/notes and embed [learning support services](#) into them. (for pre/postparation of lectures)
- ▷ **Definition 1.4.1.** Call a document [active](#), iff it is [interactive](#) and adapts to specific information needs of the readers. (course notes on steroids)
- ▷ **Intuition:** [ALEA](#) serves [active](#) course materials. (PDF mostly inactive)
- ▷ **Goal:** Make [ALEA](#) more like a teacher + study group than like a book
- ▷ **Example 1.4.2 (Course Notes).** $\hat{=}$ Slides + Comments

It is easy to see that the running time of the Prolog program from Example 5.2.9 (Programming Features) in the AI lecture notes is not $O(n \log(n))$ which is optimal for sorting algorithms. This is the flip side of the flexibility in logic programming. But Prolog has ways of dealing with that: the `cut` operator, which is a Prolog atom, which always succeeds, but which cannot be backtracked over. This can be used to prune the search tree in Prolog. We will not go into that here but refer the readers to the literature.

Specifying Control in Prolog

- ▶ **Assertion 1.1.10.** The running time of the program from Example 5.2.9 (Programming Features) in the AI lecture notes is not $O(n \log(n))$ which is optimal for sorting algorithms.
- `sort(Xs,Ys) :- perm(Xs,Ys), ordered(Ys).`
- ▶ **Idea** Gain computational efficiency by shaping the search!

Functions and Predicates in Prolog

- ▶ **Assertion 1.1.11.** Functions and predicates have radically different roles in Prolog.
- ▶ **Functions** are used to represent data. (e.g. `father(john)` or `s(s(zero))`)
- ▶ **Predicates** are used for stating properties about and computing with data.

~ yellow parts in table of contents (left) already covered in lecture.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 12 2024-02-08

The central idea in the AI4AI approach – using AI to support learning AI – and thus the ALeA system is that we want to make course materials – i.e. what we give to students for preparing and postparing lectures – more like teachers and study groups (only available 24/7) than like static books.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 13 2024-02-08

The VoLL-KI course portal (and the AI-1) home page is the central entry point for working with the ALeA system. You can get to all the components of the system, including two presentations of the course contents (notes- and slides-centric ones), the flash cards, the localized forum, and the quiz dashboard.

We now come to the heart of the ALeA system: its [learning support services](#), which we will now briefly introduce. Note that this presentation is not really sufficient to understand what you may be getting out of them, you will have to try them, and interact with them sufficiently that the [learner model](#) can get a good estimate of your [competencies](#) to adapt the results to you.

Learning Support Services in ALeA

- ▷ **Idea:** Embed [learning support services](#) into [active course materials](#).
- ▷ **Example 1.4.3 (Definition on Hover).** Hovering on a (cyan) [term reference](#) reminds us of the definition. (even works recursively)

A Conce...

Heuristic Functions

▷ **Definition 1.1.11.** Let Π be a problem with [states](#) S . A [heuristic function](#) (or short [heuristic](#)) for Π is a [function](#) $h: S \rightarrow \mathbb{R}_0^+ \cup \{\infty\}$ so that $h(s) = 0$ whenever s is a [goal state](#).

Definition 0.1. A [search problem](#) $(S, \mathcal{A}, \mathcal{J}, \mathcal{I}, g)$ consists of a [set](#) S of [states](#), a set \mathcal{A} of [actions](#), and a [transition model](#) $\mathcal{T}: \mathcal{A} \times S \rightarrow \mathcal{P}(S)$ that assigns to any action $a \in \mathcal{A}$ and state $s \in S$ a set of [successor states](#). Certain [states](#) in S are designated as [goal states](#) ($g \subseteq S$) and [initial states](#) $\mathcal{I} \subseteq S$.

Strategies [state](#), or ∞ if no such path exists, is called the [goal distance function](#) for Π .

- ▷ **Example 1.4.4 (More Definitions on Click).** Clicking on a (cyan) [term reference](#) shows us more definitions from other contexts.

▷ **Axiom 0.1 (SAT: A kind of CSP).** SAT can be viewed as a CSP problem in which all [variable domains](#) are Boolean, and the [constraints](#) have unbounded arity.

▷ **Theorem 0.1 (Encoding CSP as SAT).** Given any [constraint network](#) C , we can in low

▷ Symbol [CNF](#)

DM(de) AII(en) DM(en)

▷ A [formula](#) is in [conjunctive normal form \(CNF\)](#) if it is a [conjunction](#) of [disjunctions](#) of [literals](#): i.e. if it is of the form $\bigwedge_{i=1}^n \bigvee_{j=1}^{m_i} l_{ij}$

CLOSE

▷ **Axiom 0.1 (SAT: A kind of CSP).** SAT can be viewed as a CSP problem in which all variable domains are Boolean, and the constraints have unbounded arity.
 ▷ **Theorem 0.1 (Encoding CSP as SAT).** Given any constraint network \mathcal{C} , we can in low

Symbol CNF

DM(de) All(en) DM(en)

A **literal** is an **atomic formula** or a **negation** of one. A **formula** is said to be in

- **negation normal form (NNF)**, iff **negations** are **literals**.
- **conjunctive normal form (CNF)**, iff it is a **conjunction** of **disjunctions** of **literals**.
- **disjunctive normal form (DNF)**, iff it is a **disjunction** of **conjunctions** of **literals**.

CLOSE

▷ **Axiom 0.1 (SAT: A kind of CSP).** SAT can be viewed as a CSP problem in which all variable domains are Boolean, and the constraints have unbounded arity.
 ▷ **Theorem 0.1 (Encoding CSP as SAT).** Given any constraint network \mathcal{C} , we can in low

Symbol CNF

DM(de) All(en) DM(en)

Ein **Literal** ist eine **atomare Formel** or die **Negation** einer solchen. Wir sagen, dass eine **Formel** eine

- **Negationsnormalform (NNF)** ist, wenn alle darin vorkommenden **Negationen Literale** sind.
- **konjunktive Normalform (CNF)** ist, wenn sie eine **Konjunktion** von **Diskjunktionen** von **Literalen** ist.
- **disjunktive Normalform (DNF)** ist, wenn sie eine **Disjunktion** von **Konjunktionen** von **Literalen** ist.

CLOSE

▷ **Example 1.4.5 (Guided Tour).** A **guided tour** for a concept c assembles definitions/etc. into a self-cont.

Guided Tour

$c = \text{countable} \rightsquigarrow$

- natural number
 - conj
 - equal
 - set of pairs
 - nCartProd
 - subset
 - converse relation
 - transitive
 - relation on
 - irreflexive
 - less than
 - finite
 - countable

less than

less than > finite > countable

Needs: inset natural number nCartProd converse relation transitive

irreflexive

Definition 0.1. The $\<$ relation is the **transitive closure** of the relation $\{(n, e(n)) \mid n \in \mathbb{N}\}$, and \leq its **transitive reflexive closure**. $\>$ and \leq are the corresponding **converse relations**.

For a $\<$ and b we say that a is **less than** b .

finite

finite > countable

Needs: inset natural number less than

▷ **Definition 0.1.** We say that a set A is **finite** and has **cardinality** $\#(A) \in \mathbb{N}$, iff there is a bijective function $f: A \rightarrow \{n \in \mathbb{N} \mid n \leq \#(A)\}$.

countable

countable

Needs: natural number finite

▷ **Definition 0.1.** We say that a set A is **countably infinite**, iff there is a bijective function $f: A \rightarrow \mathbb{N}$. A set is called **countable**, iff it is **finite** or **countably infinite**.

▷ ... your idea here ... (the sky is the limit)

Note that this is only an initial collection of **learning support services**, we are constantly working on additional ones. Look out for feature notifications () on the upper right hand of the **ALeA** screen.

(Practice) Problems Everywhere

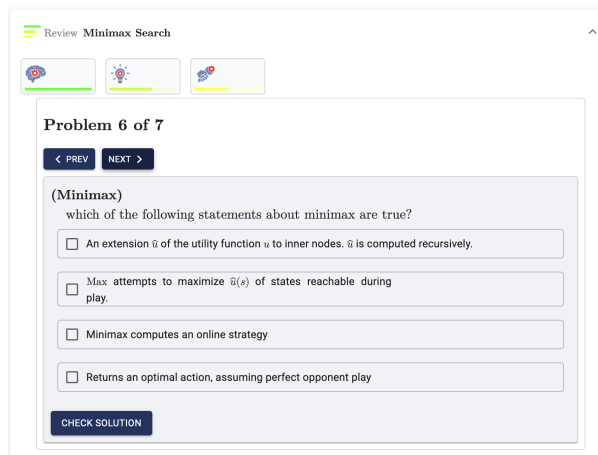

- ▷ **Problem:** Learning requires a mix of understanding and test-driven practice.
- ▷ **Idea:** ALeA supplies targeted practice problems everywhere.
- ▷ **Concretely:** Revision markers at the end of sections.
 - ▷ A relatively non-intrusive overview over competency

- ▷ Click to extend it for details.

- ▷ Practice problems as usual. (targeted to your specific competencies)

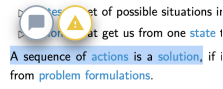

While the [learning support services](#) up to now have been addressed to individual users, we now turn to services addressed to communities of [learners](#), ranging from study groups with three [learners](#), to whole courses, and even – eventually – all the alumni of a course, if they have not de-registered from ALeA.

Currently, the community aspect of ALeA only consists in [localized interactions](#) with the course materials. The ALeA system uses the semantic structure of the course materials to [localize](#) some [interactions](#) that are otherwise often from separate applications. Here we see two:

1. one for reporting content errors – and thus making the material better for all [learners](#) – and⁴⁷
2. a [localized](#) course forum, where forum threads can be attached to [learning objects](#).

Localized Interactions with the Community

- ▷ Selecting text brings up [localized](#) – i.e. anchored on the selection – [interactions](#):

- ▷ post a (public) comment or take (private) note
- ▷ report an error to the course authors/instructors

- ▷ Localized comments induce a thread in the ALEA forum (like the StudOn Forum, but targeted towards specific learning objects)

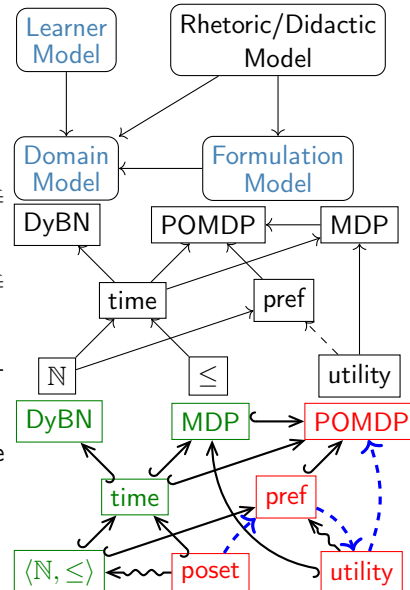

- ▷ Answering questions gives karma $\hat{=}$ a public measure of helpfulness
- ▷ Notes can be anonymous (\leadsto generate no karma)

Let us briefly look into how the learning support services introduced above might work, focusing on where the necessary information might come from. Even though some of the concepts in the discussion below may be new to students, it is worth looking into them, since they can be seen as a case study for symbolic AI, which is the main topic of our course. In this sense, bear with us as we try to explain the AI components of the ALEA system.

ALEA $\hat{=}$ Data-Driven & AI-enabled Learning Assistance

- ▷ **Idea:** Do what a teacher does!
Use/maintain four models:
- ▷ **Ingredient 1:** Domain model $\hat{=}$ knowledge/theory graph
- ▷ **Ingredient 2:** Learner model $\hat{=}$ adding competency estimations
- ▷ **Ingredient 3:** A collection of ready-formulated learning objects
- ▷ **Ingredient 4:** Educational dialogue planner \leadsto guided tours

(Good) teachers

- ▷ understand the objects and their properties they are talking about
- ▷ have readimade formulations how to convey them best
- ▷ and understand how these best work together
- ▷ model what the learners already know/understand and adapts them accordingly

A theory graph provides (modular representation of the domain)

- ▷ symbols with URIs for all concepts, objects, and relations
- ▷ definitions, notations, and verbalizations for all symbols
- ▷ “object-oriented inheritance” and views between theories.

The learner model is a function from learner IDs × symbol URIs to competency values

- ▷ competency comes in six cognitive dimensions: remember, understand, analyze, evaluate, apply, and create.
- ▷ ALeA logs all learner interactions (keeps data learner-private)
- ▷ each interaction updates the learner model function.

Learning objects are the text fragments learners see and interact with; they are structured by

- ▷ didactic relations, e.g. tasks have prerequisites and learning objectives
- ▷ rhetoric relations, e.g. introduction, elaboration, and transition

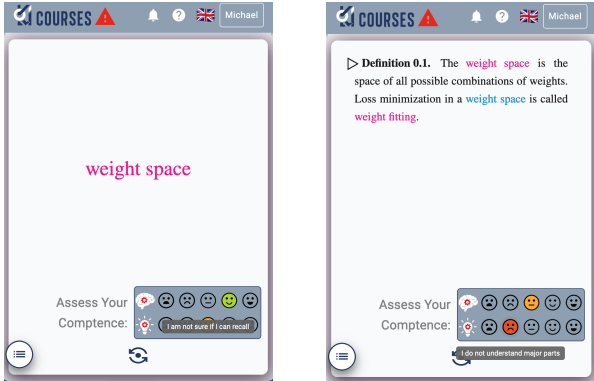

The dialogue planner assembles learning objects into active course materials using

- ▷ the domain model and didactic relations to determine the order of LOs
- ▷ the learner model to determine what to show
- ▷ the rhetoric relations to make the dialogue coherent

We can use the same four models discussed in the space of guided tours to deploy additional learning support services, which we now discuss.

New Feature: Drilling with Flashcards

- ▷ Flashcards challenge you with a task (term/problem) on the front. . .

... and the definition/answer is on the **back**.

- ▷ **Self-assessment** updates the **learner model** (before/after)
- ▷ **Idea:** Challenge yourself to a **card stack**, keep drilling/assessing **flashcards** until the **learner model** eliminates all.
- ▷ **Bonus:** **Flashcards** can be generated from existing semantic markup (**educational equivalent to free beer**)

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 18 2024-02-08

We have already seen above how the **learner model** can drive the **drilling** with **flashcards**. It can also be used for the configuration of **card stacks** by configuring a domain e.g. a section in the course materials and a **competency** threshold. We now come to a very important issue that we always face when we do AI systems that interface with humans. Most Web technology companies that take one the approach “the user pays for the services with their **personal data**, which is sold on” or integrate advertising for remuneration. Both are not acceptable in university setting.

But abstaining from monetizing **personal data** still leaves the problem how to protect it from intentional or accidental misuse. Even though the **GDPR** has quite extensive exceptions for research, the **ALeA** system – a research prototype – adheres to the principles and mandates of the **GDPR**. In particular it makes sure that **personal data** of the **learners** is only used in **learning support services** directly or indirectly initiated by the **learners** themselves.

Learner Data and Privacy in ALeA

- ▷ **Observation:** Most **learning support services** in **ALeA** use the **learner model**; they
 - ▷ need the **learner model** data to adapt to the individual **learner**!
 - ▷ collect **learner** interaction data (to update the **learner model**)
- ▷ **Consequence:** You need to be **logged in** (via your **FAU IDM** credentials) for useful **learning support services**!
- ▷ **Problem:** **Learner model** data is highly sensitive personal data!
- ▷ **ALeA Promise:** The **ALeA** team does the utmost to keep your personal data safe. (SSO via **FAU IDM/eduGAIN**, **ALeA trust zone**)
- ▷ **ALeA Privacy Axioms:**

1. **ALEA** only collects **learner models** data about logged in users.
 2. Personally identifiable **learner model** data is only accessible to its subject (**delegation possible**)
 3. **Learners** can always query the **learner model** about its data.
 4. All **learner model** data can be purged without negative consequences (except usability deterioration)
 5. Logging into **ALEA** is completely optional.
- ▷ **Observation:** Authentication for bonus quizzes are somewhat less optional, but you can always purge the **learner model** later.

Concrete Todos for ALeA

- ▷ **Recall:** You will use **ALeA** for the **tuesday quizzes** (or lose bonus points)
All other use is optional (but AI-supported pre/postparation can be helpful)
- ▷ To use the **ALeA** system, you will have to **log in** via **SSO** (do it now)
- ▷ go to `https://courses.voll-ki.fau.de/course-home/ai-1`
 - ▷ in the upper right hand corner you see 
 - ▷ **log in** via your **FAU IDM** credentials. (you should have them by now)
 - ▷ You get access to your personal **ALeA** profile via 
(plus feature notifications, manual, and language chooser)
- ▷ **Problem:** Most **ALeA** services depend on the **learner model** (to adapt to you)
- ▷ **Solution:** Initialize your **learner model** with your educational history!
- ▷ **Concretely:** enter taken **CS** courses (FAU equivalents) and grades
 - ▷ **ALeA** uses that to estimate your **CS/AI** competencies (for your benefit)
 - ▷ then **ALeA** knows about you; I don't (ALeA trust zone)

Chapter 2

Artificial Intelligence – Who?, What?, When?, Where?, and Why?

We start the course by giving an overview of (the problems, methods, and issues of) [Artificial Intelligence](#), and what has been achieved so far.

Naturally, this will dwell mostly on philosophical aspects – we will try to understand what the important issues might be and what questions we should even be asking. What the most important avenues of attacks may be and where [AI](#) research is being carried out.

In particular the discussion will be very non-technical – we have very little basis to discuss technicalities yet. But stay with me, this will drastically change very soon. [A Video Nugget](#) covering the introduction of this chapter can be found at <https://fau.tv/clip/id/21467>.

Plot for this chapter

- ▷ Motivation, overview, and finding out what you already know
 - ▷ What is [Artificial Intelligence](#)?
 - ▷ What has [AI](#) already achieved?
 - ▷ A (very) quick walk through the AI-1 topics.
 - ▷ How can you get involved with [AI](#) at [KWARC](#)?

 FRIEDRICH-ALEXANDER
UNIVERSITÄT
ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 21 2024-02-08 

2.1 What is Artificial Intelligence?

[A Video Nugget](#) covering this section can be found at <https://fau.tv/clip/id/21701>.

The first question we have to ask ourselves is “What is [Artificial Intelligence](#)?”, i.e. how can we define it. And already that poses a problem since the natural definition *like human intelligence, but artificially realized* presupposes a definition of [intelligence](#), which is equally problematic; even Psychologists and Philosophers – the subjects nominally “in charge” of [natural intelligence](#) – have problems defining it, as witnessed by the plethora of theories e.g. found at [WHI].

[What is Artificial Intelligence? Definition](#)

- ▷ **Definition 2.1.1 (According to Wikipedia).** Artificial Intelligence (AI) is intelligence exhibited by machines
- ▷ **Definition 2.1.2 (also).** Artificial Intelligence (AI) is a sub-field of computer science that is concerned with the automation of intelligent behavior.
- ▷ **BUT:** it is already difficult to define intelligence precisely.
- ▷ **Definition 2.1.3 (Elaine Rich).** Artificial Intelligence (AI) studies how we can make the computer do things that humans can still do better at the moment.

Maybe we can get around the problems of defining “what artificial intelligence is”, by just describing the necessary components of AI (and how they interact). Let’s have a try to see whether that is more informative.

What is Artificial Intelligence? Components

- ▷ **Elaine Rich:** AI studies how we can make the computer do things that humans can still do better at the moment.
- ▷ This needs a combination of

the ability to learn

Inference

Perception

Language understanding

Emotion

Note that list of components is controversial as well. Some say that it lumps together cognitive capacities that should be distinguished or forgets others, We state it here much more to get AI-1 students to think about the issues than to make it normative.

2.2 Artificial Intelligence is here today!

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/21697>. The components of **Artificial Intelligence** are quite daunting, and none of them are fully understood, much less achieved artificially. But for some tasks we can get by with much less. And indeed that is what the field of **Artificial Intelligence** does in practice – but keeps the lofty ideal around. This practice of “trying to achieve **AI** in selected and restricted domains” (cf. the discussion starting with slide 31) has borne rich fruits: systems that meet or exceed human capabilities in such areas. Such systems are in common use in many domains of application.

Artificial Intelligence is here today!

- ▷ in outer space
 - ▷ in outer space systems need autonomous control:
 - ▷ remote control impossible due to time lag
- ▷ in artificial limbs
 - ▷ the user controls the prosthesis via existing nerves, can e.g. grip a sheet of paper.
- ▷ in household appliances
 - ▷ The iRobot Roomba vacuums, mops, and sweeps in corners, . . . , parks, charges, and discharges.
 - ▷ general robotic household help is on the horizon.
- ▷ in hospitals
 - ▷ in the USA 90% of the prostate operations are carried out by RoboDoc
 - ▷ Paro is a cuddly robot that eases solitude in nursing homes.

And here's what you all have been waiting for ...

CC-BY-SA: Buster Benson@

<https://www.flickr.com/photos/erikbenson/25717574115>

- ▷ **AlphaGo** is a program by Google DeepMind to play the board game **go**.
- ▷ In March 2016, it beat Lee Sedol in a five-game match, the first time a **go program** has beaten a 9 dan professional without handicaps. In December 2017 **AlphaZero**, a successor of **AlphaGo** “learned” the games **go**, **chess**, and shogi in 24 hours, achieving a superhuman level of play in these three games by defeating world-champion programs. By September 2019, **AlphaStar**, a variant of **AlphaGo**, attained “grandmaster level” in Starcraft II, a real time strategy game with partially observable state. **AlphaStar** now among the top 0.2% of human players.

We will conclude this section with a note of caution.

The AI Conundrum

- ▷ **Observation:** Reserving the term “**Artificial Intelligence**” has been quite a land grab!
- ▷ **But:** researchers at the **Dartmouth Conference** (1956) really thought they would solve/reach **AI** in two/three decades.
- ▷ **Consequence:** **AI** still asks the big questions.
- ▷ **Another Consequence:** **AI** as a field is an incubator for many innovative technologies.
- ▷ **AI Conundrum:** Once **AI** solves a subfield it is called “**computer science**”.
(becomes a separate subfield of CS)
- ▷ **Example 2.2.1.** Functional/Logic Programming, **automated theorem proving**, Planning, **machine learning**, Knowledge Representation, ...
- ▷ **Still Consequence:** **AI** research was alternatingly flooded with money and cut off brutally.

2.3 Ways to Attack the AI Problem

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/21717>.

There are currently three main avenues of attack to the problem of building **artificially intelligent systems**. The (historically) first is based on the symbolic representation of knowledge about the world and uses inference-based methods to derive new knowledge on which to base action decisions. The second uses statistical methods to deal with **uncertainty** about the world state and learning methods to derive new (**uncertain**) world assumptions to act on.

Four Main Approaches to Artificial Intelligence

- ▷ **Definition 2.3.1.** **Symbolic AI** is a subfield of **AI** based on the assumption that many aspects of **intelligence** can be achieved by the manipulation of **symbols**, combining them into **meaning-carrying structures (expressions)** and manipulating them (using processes) to produce new **expressions**.
- ▷ **Definition 2.3.2.** **Statistical AI** remedies the two shortcomings of **symbolic AI** approaches: that all concepts represented by **symbols** are crisply defined, and that all aspects of the world are knowable/representable in principle. **Statistical AI** adopts sophisticated **mathematical models** of **uncertainty** and uses them to create more accurate world models and reason about them.
- ▷ **Definition 2.3.3.** **Subsymbolic AI** (also called **connectionism** or **neural AI**) is a subfield of **AI** that posits that **intelligence** is inherently tied to brains, where information is represented by a simple sequence pulses that are processed in parallel via simple calculations realized by neurons, and thus concentrates on neural computing.
- ▷ **Definition 2.3.4.** **Embodied AI** posits that **intelligence** cannot be achieved by **reasoning** about the state of the world (**symbolically, statistically, or connectivist**), but must be **embodied** i.e. situated in the world, equipped with a “body” that can interact with it via **sensors** and **actuators**. Here, the main method for realizing **intelligent behavior** is by **learning** from the world.

As a consequence, the field of **Artificial Intelligence (AI)** is an engineering field at the intersection of **computer science** (logic, **programming**, applied statistics), cognitive science (psychology, neuroscience), philosophy (can machines think, what does that mean?), linguistics (**natural language understanding**), and mechatronics (robot hardware, sensors).

Subsymbolic AI and in particular **machine learning** is currently hyped to such an extent, that many people take it to be synonymous with “Artificial Intelligence”. It is one of the goals of this course to show students that this is a very impoverished view.

Two ways of reaching Artificial Intelligence?

- ▷ We can classify the **AI** approaches by their coverage and the analysis depth (**they are complementary**)

Deep	symbolic AI-1	not there yet cooperation?
Shallow	no-one wants this	statistical/sub symbolic AI-2
Analysis ↑ vs. Coverage →	Narrow	Wide

- ▷ **This semester** we will cover foundational aspects of **symbolic AI** (deep/narrow processing)
- ▷ **next semester** concentrate on **statistical/subsymbolic AI**. (shallow/wide-coverage)

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG

Michael Kohlhase: Artificial Intelligence 1 28 2024-02-08

We combine the topics in this way in this course, not only because this reproduces the historical development but also as the methods of **statistical** and **subsymbolic AI** share a common basis. It is important to notice that all approaches to **AI** have their application domains and strong points. We will now see that exactly the two areas, where **symbolic AI** and **statistical/subsymbolic AI** have their respective fortes correspond to natural application areas.

Environmental Niches for both Approaches to AI

- ▷ **Observation:** There are two kinds of applications/tasks in **AI**
 - ▷ **Consumer tasks:** consumer grade applications have tasks that must be fully generic and wide coverage. (e.g. machine translation like Google Translate)
 - ▷ **Producer tasks:** producer grade applications must be high-precision, but can be domain-specific (e.g. multilingual documentation, machinery-control, program verification, medical technology)

Precision			
100%	Producer Tasks		
50%		Consumer Tasks	
	$10^{3\pm 1}$ Concepts	$10^{6\pm 1}$ Concepts	Coverage

- ▷ **General Rule:** **Subsymbolic AI** is well suited for **consumer tasks**, while **symbolic AI** is better suited for **producer tasks**.
- ▷ A domain of **producer tasks** I am interested in: **mathematical/technical documents**.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG

Michael Kohlhase: Artificial Intelligence 1 29 2024-02-08

An example of a producer task – indeed this is where the name comes from – is the case of a machine tool manufacturer T , which produces digitally programmed machine tools worth multiple million Euro and sells them into dozens of countries. Thus T must also comprehensive machine

operation manuals, a non-trivial undertaking, since no two machines are identical and they must be translated into many languages, leading to hundreds of documents. As those manual share a lot of semantic content, their management should be supported by AI techniques. It is critical that these methods maintain a high precision, operation errors can easily lead to very costly machine damage and loss of production. On the other hand, the domain of these manuals is quite restricted. A machine tool has a couple of hundred components only that can be described by a couple of thousand attribute only.

Indeed companies like *T* employ high-precision AI techniques like the ones we will cover in this course successfully; they are just not so much in the public eye as the [consumer tasks](#).

To get this out of the way ...

CC-BY-SA: Buster Benson@ <https://www.flickr.com/photos/erikbenson/25717574115>

- ▷ AlphaGo = search + neural networks (symbolic + subsymbolic AI)
 - ▷ we do search this semester and cover neural networks in AI-2.
 - ▷ I will explain AlphaGo a bit in chapter 7.

2.4 Strong vs. Weak AI

A [Video Nugget](https://fau.tv/clip/id/21724) covering this section can be found at <https://fau.tv/clip/id/21724>.

To get this out of the way before we begin: We now come to a distinction that is often muddled in popular discussions about “Artificial Intelligence”, but should be cristal clear to students of the course AI-1 – after all, you are upcoming “AI-specialists”.

Strong AI vs. Narrow AI

- ▷ **Definition 2.4.1.** With the term **narrow AI** (also **weak AI**, **instrumental AI**, **applied AI**) we refer to the use of software to study or accomplish *specific* problem solving or reasoning tasks (e.g. **playing chess/go**, **controlling elevators**, **composing music**, ...)
- ▷ **Definition 2.4.2.** With the term **strong AI** (also **full AI**, **AGI**) we denote the quest for software performing at the full range of human cognitive abilities.
- ▷ **Definition 2.4.3.** Problems requiring **strong AI** to solve are called **AI hard**.

- ▷ **In short:** We can characterize the difference intuitively:
 - ▷ **narrow AI:** What (most) **computer scientists** think AI is / should be.
 - ▷ **strong AI:** What **Hollywood** authors think AI is / should be.
- ▷ **Needless to say** we are only going to cover **narrow AI** in this course!

One can usually defuse public worries about “is AI going to take control over the world” by just explaining the difference between **strong AI** and **weak AI** clearly.

I would like to add a few words on **AGI**, that – if you adopt them; they are not universally accepted – will strengthen the arguments differentiating between **strong** and **weak AI**.

A few words on AGI...

- ▷ The conceptual and **mathematical** framework (agents, environments etc.) is the same for **strong AI** and **weak AI**.
- ▷ **AGI** research focuses mostly on abstract aspects of machine learning (reinforcement learning, neural nets) and decision/game theory (“which goals should an AGI pursue?”).
- ▷ Academic respectability of **AGI** fluctuates massively, recently increased (again).
(**correlates somewhat with AI winters and golden years**)
- ▷ Public attention increasing due to talk of “existential risks of **AI**” (e.g. **Hawking, Musk, Bostrom, Yudkowsky, Obama, ...**)
- ▷ **Kohlhase’s View:** **Weak AI** is here, **strong AI** is very far off. (**not in my lifetime**)
But even if that is true, **weak AI** will affect all of us deeply in everyday life.
- ▷ **Example 2.4.4.** You should not train to be an accountant or truck driver!
(**bots will replace you**)

I want to conclude this section with an overview over the recent protagonists – both personal and institutional – of **AGI**.

AGI Research and Researchers

- ▷ “Famous” research(ers) / organizations
 - ▷ MIRI (Machine Intelligence Research Institute), Eliezer Yudkowsky (**Formerly known as “Singularity Institute”**)
 - ▷ Future of Humanity Institute Oxford (Nick Bostrom),
 - ▷ Google (Ray Kurzweil),
 - ▷ AGIRI / OpenCog (Ben Goertzel),
 - ▷ petr1.org (People for the Ethical Treatment of Reinforcement Learners).
(**Obviously somewhat tongue-in-cheek**)
- ▷  Be highly skeptical about any claims with respect to **AGI!** (**Kohlhase’s View**)

2.5 AI Topics Covered

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/21719>.

We will now preview the topics covered by the course “Artificial Intelligence” in the next two semesters.

Topics of AI-1 (Winter Semester)

- ▷ Getting Started
 - ▷ What is **Artificial Intelligence?** (situating ourselves)
 - ▷ **Logic programming in Prolog** (An influential paradigm)
 - ▷ **Intelligent Agents** (a unifying framework)
- ▷ Problem Solving
 - ▷ Problem Solving and **search** (Black Box World States and Actions)

AI1SysProj: A Systems/Project Supplement to AI-1

- ▷ The AI-1 course concentrates on concepts, theory, and algorithms of symbolic AI.
- ▷ **Problem:** Engineering/Systems Aspects of AI are very important as well.
- ▷ **Partial Solution:** Getting your hands dirty in the homeworks and the Kalah Challenge
- ▷ **Full Solution:** AI1SysProj: AI-1 Systems Project (10 ECTS, 30-50places)
 - ▷ For each Topic of AI-1, there will be a mini-project in AI1SysProj
 - ▷ e.g. for game-play there will be Chinese Checkers (more difficult than Kalah)
 - ▷ e.g. for CSP we will schedule TechFak courses or exams (from real data)
 - ▷ solve challenges by implementing the AI-1 algorithms or use SoA systems
- ▷ **Question:** Should I take AI1SysProj in my first semester? (i.e. now)
- ▷ **Answer:** It depends ... (on your situation)
 - ▷ most master's programs require a 10-ECTS "Master's Project" (Master AI: two)
 - ▷ there will be a great pressure on project places (so reserve one early)
 - ▷ BUT 10 ECTS $\hat{=}$ 250-300 hours involvement by definition (1/3 of your time/ECTS)
- ▷ **BTW:** There will also be an AI2SysProj next semester! (another chance)

2.6 AI in the KWARC Group

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/21725>.

Now allow me to beat my own drum. In my research group at FAU, we do research on a particular kind of **Artificial Intelligence**: logic, language, and information. This may not be the most fashionable or well-hyped area in AI, but it is challenging, well-respected, and – most importantly – fun.

The KWARC Research Group

- ▷ **Observation:** The ability to **represent knowledge** about the world and to **draw logical inferences** is one of the central components of **intelligent behavior**.
- ▷ **Thus:** reasoning components of some form are at the heart of many AI systems.
- ▷ **KWARC Angle:** Scaling up (web-coverage) without dumbing down (too much)
 - ▷ **Content markup** instead of full formalization (too tedious)
 - ▷ **User support** and **quality control** instead of “The Truth” (elusive anyway)
 - ▷ use **Mathematics** as a test tube (\triangle **Mathematics** $\hat{=}$ **Anything Formal** \triangle)
 - ▷ care more about applications than about philosophy (we cannot help getting this right anyway as logicians)
- ▷ The **KWARC** group was established at Jacobs Univ. in 2004, moved to FAU Erlangen in 2016
- ▷ see <http://kwarc.info> for projects, publications, and links

Michael Kohlhase: Artificial Intelligence 1
37
2024-02-08

Research in the **KWARC** group ranges over a variety of topics, which range from foundations of **mathematics** to relatively applied web information systems. I will try to organize them into three pillars here.

Overview: KWARC Research and Projects

Applications: eMath 3.0, Active Documents, Active Learning, Semantic Spreadsheets/CAD/CAM, Change Management, Global Digital Math Library, Math Search Systems, **SMGloM:** Semantic Multilingual Math Glossary, Serious Games, ...

Foundations of Math:	KM & Interaction:	Semantization:
<ul style="list-style-type: none"> ▷ MathML, OpenMath ▷ advanced Type Theories ▷ MMT: Meta Meta Theory ▷ Logic Morphisms/Atlas ▷ Theorem Prover/CAS Interoperability ▷ Mathematical Models/Simulation 	<ul style="list-style-type: none"> ▷ Semantic Interpretation (aka. Framing) ▷ math-literate interaction ▷ MathHub: math archives & active docs ▷ Active documents: embedded semantic services ▷ Model-based Education 	<ul style="list-style-type: none"> ▷ LaTeXML: LaTeX \rightarrow XML ▷ STeX: Semantic LaTeX ▷ invasive editors ▷ Context-Aware IDEs ▷ Mathematical Corpora ▷ Linguistics of Math ▷ ML for Math Semantics Extraction

Foundations: Computational Logic, Web Technologies, **OMDoc/MMT**

Michael Kohlhase: Artificial Intelligence 1
38
2024-02-08

For all of these areas, we are looking for bright and motivated students to work with us. This can take various forms, theses, internships, and paid student assistantships.

Research Topics in the KWARC Group

- ▷ We are always looking for bright, motivated KWARCies.
- ▷ We have topics in for all levels! (Enthusiast, Bachelor, Master, Ph.D.)

- ▷ List of current topics: <https://gl.kwarc.info/kwarc/thesis-projects/>
 - ▷ Automated Reasoning: Maths Representation in the Large
 - ▷ Logics development, (Meta)ⁿ-Frameworks
 - ▷ Math Corpus Linguistics: Semantics Extraction
 - ▷ Serious Games, Cognitive Engineering, Math Information Retrieval, Legal Reasoning, ...
- ▷ We always try to find a topic at the intersection of your and our interests.
- ▷ We also often have positions! (HiWi, Ph.D.: $\frac{1}{2}$, PostDoc: full)

Sciences like physics or geology, and engineering need high-powered equipment to perform measurements or experiments. **computer science** and in particular the **KWARC** group needs high powered human brains to build systems and conduct thought experiments.

The **KWARC** group may not always have as much funding as other **AI** research groups, but we are very dedicated to give the best possible research guidance to the students we supervise.

So if this appeals to you, please come by and talk to us.

Part I

Getting Started with AI: A Conceptual Framework

This part of the course note sets the stage for the technical parts of the course by establishing a common framework (Rational Agents) that gives context and ties together the various methods discussed in the course.

After having seen what AI can do and where AI is being employed today (see chapter 2), we will now

1. introduce a [programming language](#) to use in the course,
2. prepare a conceptual framework in which we can think about “[intelligence](#)” ([natural](#) and [artificial](#)), and
3. recap some methods and results from theoretical [computer science](#) that we will need throughout the course.

ad 1. Prolog: For the [programming language](#) we choose [Prolog](#), historically one of the most influential “[AI programming languages](#)”. While the other [AI programming language](#): [Lisp](#) which gave rise to the [functional programming programming paradigm](#) has been superseded by typed languages like [SML](#), [Haskell](#), [Scala](#), and [F#](#), [Prolog](#) is still the prime example of the [declarative programming paradigm](#). So using [Prolog](#) in this course gives students the opportunity to explore this [paradigm](#). At the same time, [Prolog](#) is well-suited for trying out [algorithms](#) in [symbolic AI](#) the topic of this semester since it internalizes the more complex primitives of the [algorithms](#) presented here.

ad 2. Rational Agents: The conceptual framework centers around [rational agents](#) which combine aspects of purely cognitive architectures (an original concern for the field of [AI](#)) with the more recent realization that intelligence must interact with the world ([embodied AI](#)) to grow and learn. The cognitive architectures aspect allows us to place and relate the various [algorithms](#) and methods we will see in this course. Unfortunately, the “situated AI” aspect will not be covered in this course due to the lack of time and hardware.

ad 3. Topics of Theoretical Computer Science: When we evaluate the methods and [algorithms](#) introduced in AI-1, we will need to judge their suitability as [agent functions](#). The main theoretical tool for that is [complexity theory](#); we will give a short motivation and overview of the main methods and results as far as they are relevant for AI-1 in section 4.1.

In the second half of the semester we will transition from search-based methods for problem solving to inference-based ones, i.e. where the problem formulation is described as [expressions](#) of a [formal language](#) which are transformed until an [expression](#) is reached from which the solution can be read off. [Phrase structure grammars](#) are the method of choice for describing such languages; we will introduce/recap them in section 4.2.

Enough philosophy about “Intelligence” (Artificial or Natural)

- ▷ So far we had a nice philosophical chat, about “[intelligence](#)” et al.
- ▷ As of today, we look at technical stuff!
- ▷ Before we go into the [algorithms](#) and [data structures](#) proper, we will
 1. introduce a [programming language](#) for AI-1
 2. prepare a conceptual framework in which we can think about “[intelligence](#)” ([natural](#) and [artificial](#)), and
 3. recap some methods and results from theoretical [computer science](#).

Chapter 3

Logic Programming

We will now learn a new programming paradigm: logic programming, which is one of the most influential paradigms in AI. We are going to study Prolog (the oldest and most widely used) as a concrete example of ideas behind logic programming and use it for our homeworks in this course.

As Prolog is a representative of a programming paradigm that is new to most students, programming will feel weird and tedious at first. But subtracting the unusual syntax and program organization logic programming really only amounts to recursive programming just as in functional programming (the other declarative programming paradigm). So the usual advice applies, keep staring at it and practice on easy examples until the pain goes away.

3.1 Introduction to Logic Programming and ProLog

Logic programming is a programming paradigm that differs from functional and imperative programming in the basic procedural intuition. Instead of transforming the state of the memory by issuing instructions (as in imperative programming), or computing the value of a function on some arguments, logic programming interprets the program as a body of knowledge about the respective situation, which can be queried for consequences.

This is actually a very natural conception of program; after all we usually run (imperative or functional) programs if we want some question answered. Video Nuggets covering this section can be found at <https://fau.tv/clip/id/21752> and <https://fau.tv/clip/id/21753>.

Logic Programming

- ▷ **Idea:** Use logic as a programming language!
- ▷ We state what we know about a problem (the program) and then ask for results (what the program would compute).
- ▷ **Example 3.1.1.**

Program	Leibniz is human Sokrates is human Sokrates is a greek Every human is fallible	$x + 0 = x$ If $x + y = z$ then $x + s(y) = s(z)$ 3 is prime
Query	Are there fallible greeks?	is there a z with $s(s(0)) + s(0) = z$
Answer	Yes, Sokrates!	yes $s(s(s(0)))$

- ▷ **How to achieve this?** Restrict a logic calculus sufficiently that it can be used as computational procedure.
- ▷ **Remark:** This idea leads a totally new programming paradigm: logic programming.
- ▷ **Slogan:** Computation = Logic + Control (Robert Kowalski 1973; [Kow97])
- ▷ We will use the programming language Prolog as an example.

We now formally define the language of Prolog, starting off the atomic building blocks.

Prolog Terms and Literals

- ▷ **Definition 3.1.2.** Prologs expresses knowledge about the world via
 - ▷ constants denoted by lower case strings,
 - ▷ variables denoted by upper-case strings or starting with `_`, and
 - ▷ functions and predicates (lower-case strings) applied to terms.

- ▷ **Definition 3.1.3.** A Prolog term is
 - ▷ a Prolog variable, or constant, or
 - ▷ a Prolog function applied to terms.

A Prolog literal is a constant or a predicate applied to terms.

- ▷ **Example 3.1.4.** The following are
 - ▷ Prolog terms: john, X, `_`, father(john), ...
 - ▷ Prolog literals: loves(john,mary), loves(john,`_`), loves(john,wife_of(john)),...

Now we build up Prolog programs from those building blocks.

Prolog Programs: Facts and Rules

- ▷ **Definition 3.1.5.** A Prolog program is a sequence of clauses, i.e.
 - ▷ facts of the form $l.$, where l is a literal, (a literal and a dot)
 - ▷ rules of the form $h:-b_1,\dots,b_n.$, where h is called the head literal (or simply head) and the b_i are together called the body of the rule.

A rule $h: b_1,\dots,b_n.$ should be read as h (is true) if b_1 and ... and b_n are.

- ▷ **Example 3.1.6.** Write “something is a car if it has a motor and four wheels” as $\text{car}(X) :- \text{has_motor}(X), \text{has_wheels}(X,4).$ (variables are upper-case) this is just an ASCII notation for $m(x) \wedge w(x,4) \Rightarrow \text{car}(x)$

- ▷ **Example 3.1.7.** The following is a Prolog program:

```
human(leibniz).
human(sokrates).
```

```
greek(sokrates).
fallible(X):-human(X).
```

The first three lines are **Prolog facts** and the last a **rule**.

The whole point of writing down a **knowledge base** (a **Prolog program** with **knowledge** about the situation), if we do not have to write down *all* the **knowledge**, but a (small) subset, from which the rest follows. We have already seen how this can be done: with **logic**. For **logic programming** we will use a **logic** called “**first-order logic**” which we will not formally introduce here.

Prolog Programs: Knowledge bases

- ▷ **Intuition:** The **knowledge base** given by a **Prolog program** is the set of **facts** that can be derived from it under the if/and reading above.
- ▷ **Definition 3.1.8.** The **knowledge base** given by **Prolog** program is that set of **facts** that can be **derived** from it by Modus Ponens (**MP**), $\wedge I$ and instantiation.

$$\frac{A \quad A \Rightarrow B}{B} \text{MP} \qquad \frac{A \quad B}{A \wedge B} \wedge I \qquad \frac{A}{[B/X](A)} \text{Subst}$$

?? introduces a very important distinction: that between a **Prolog program** and the **knowledge base** it induces. Whereas the former is a **finite**, syntactic object (essentially a string), the latter may be an **infinite** set of **facts**, which represents the totality of knowledge about the world or the aspects described by the **program**.

As **knowledge bases** can be **infinite**, we cannot pre compute them. Instead, **logic programming** languages compute fragments of the **knowledge base** by need; i.e. whenever a user wants to check membership; we call this approach **querying**: the user enters a **query expression** and the system answers yes or no. This answer is computed in a **depth first search** process.

Querying the Knowledge Base: Size Matters

- ▷ **Idea:** We want to see whether a **fact** is in the **knowledge base**.
- ▷ **Definition 3.1.9.** A **query** is a list of **Prolog terms** called **goal literal** (also **subgoals** or simply **goals**). We write a **query** as $?-A_1, \dots, A_n$. where A_i are **goals**.
- ▷ **Problem:** **Knowledge bases** can be big and even **infinite**. (cannot pre compute)
- ▷ **Example 3.1.10.** The **knowledge base** induced by the **Prolog program**

```
nat(zero).
nat(s(X)) :- nat(X).
```

contains the **facts** $\text{nat}(\text{zero}), \text{nat}(\text{s}(\text{zero})), \text{nat}(\text{s}(\text{s}(\text{zero}))), \dots$

Querying the Knowledge Base: Backchaining

- ▷ **Definition 3.1.11.** Given a **query** $Q: ?- A_1, \dots, A_n.$ and **rule** $R: h:- b_1, \dots, b_n,$ **backchaining** computes a new **query** by
 1. finding **terms** for all **variables** in h to make h and A_1 equal and
 2. replacing A_1 in Q with the **body literals** of R , where all **variables** are suitably replaced.
- ▷ **Backchaining** motivates the names **goal/subgoal**:
 - ▷ the **literals** in the **query** are “**goals**” that have to be satisfied,
 - ▷ **backchaining** does that by replacing them by new “**goals**”.
- ▷ **Definition 3.1.12.** The **Prolog interpreter** keeps **backchaining** from the top to the bottom of the **program** until the **query**
 - ▷ **succeeds**, i.e. contains no more **goals**, or (answer: **true**)
 - ▷ **fails**, i.e. **backchaining** becomes impossible. (answer: **false**)
- ▷ **Example 3.1.13 (Backchaining).** We continue Example 3.1.10

```
?- nat(s(s(zero))).
?- nat(s(zero)).
?- nat(zero).
true
```

Note that **backchaining** replaces the current **query** with the body of the rule suitably instantiated. For rules with a long body this extends the list of current **goals**, but for **facts** (**rules** without a **body**), **backchaining** shortens the list of current **goals**. Once there are no **goals** left, the **Prolog interpreter** finishes and signals **success** by issuing the string **true**.

If no rules **match** the current **subgoal**, then the **interpreter terminates** and signals **failure** with the string **false**,

Querying the Knowledge Base: Failure

- ▷ If no instance of a **query** can be derived from the **knowledge base**, then the **Prolog interpreter** reports **failure**.
- ▷ **Example 3.1.14.** We vary Example 3.1.13 using 0 instead of zero.

```
?- nat(s(s(0))).
?- nat(s(0)).
?- nat(0).
FAIL
false
```

We can extend **querying** from simple yes/no answers to programs that return values by simply using **variables** in **queries**. In this case, the **Prolog interpreter** returns a **substitution**.

Querying the Knowledge base: Answer Substitutions

▷ **Definition 3.1.15.** If a **query** contains **variables**, then **Prolog** will return an **answer substitution** as the **result** to the **query**, i.e the **values** for all the **query variables** accumulated during repeated **backchaining**.

▷ **Example 3.1.16.** We talk about (Bavarian) cars for a change, and use a **query** with a **variables**

```
has_wheels(mybmw,4).
has_motor(mybmw).
car(X):-has_wheels(X,4),has_motor(X).
?- car(Y) % query
?- has_wheels(Y,4),has_motor(Y). % substitution X = Y
?- has_motor(mybmw). % substitution Y = mybmw
Y = mybmw % answer substitution
true
```

In ?? the first **backchaining** step binds the variable **X** to the **query** variable **Y**, which gives us the two **subgoals** **has_wheels(Y,4),has_motor(Y)**. which again have the **query variable** **Y**. The next **backchaining** step binds this to **mybmw**, and the third **backchaining** step exhausts the **subgoals**. So the **query succeeds** with the (overall) **answer substitution** **Y = mybmw**. With this setup, we can already do the “fallible Greeks” example from the introduction.

PROLOG: Are there Fallible Greeks?

▷ **Program:**

```
human(leibniz).
human(sokrates).
greek(sokrates).
fallible(X):-human(X).
```

▷ **Example 3.1.17 (Query).** `?-fallible(X),greek(X).`

▷ **Answer substitution:** `[sokrates/X]`

3.2 Programming as Search

In this section, we want to really use **Prolog** as a **programming language**, so let use first get our tools set up. **Video Nuggets** covering this section can be found at <https://fau.tv/clip/id/21754> and <https://fau.tv/clip/id/21827>.

3.2.1 Running Prolog

We will now discuss how to use a **Prolog interpreter** to get to know the language. The **SWI Prolog interpreter** can be downloaded from <http://www.swi-prolog.org/>. To start the **Prolog interpreter** with `pl` or `prolog` or `swipl` from the **shell**. The **SWI manual** is available at <http://www.swi-prolog.org/pldoc/>

We will introduce working with the [interpreter](#) using unary natural numbers as examples: we first add the [fact](#)¹ to the [knowledge base](#)

```
umat(zero).
```

which asserts that the [predicate](#) `umat`² is **true** on the term `zero`. Generally, we can add a [fact](#) to the knowledge base either by writing it into a file (e.g. `example.pl`) and then “consulting it” by writing one of the following three commands into the [interpreter](#):

```
[example]
consult('example.pl').
consult('example').
```

or by directly typing

```
assert(umat(zero)).
```

into the [Prolog interpreter](#). Next tell [Prolog](#) about the following rule

```
assert(umat(suc(X)) :- umat(X)).
```

which gives the [Prolog runtime](#) an initial (infinite) [knowledge base](#), which can be queried by

```
?- umat(suc(suc(zero))).
```

Even though we can use any text editor to program [Prolog](#), but running [Prolog](#) in a modern editor with language support is incredibly nicer than at the [command line](#), because you can see the whole history of what you have done. Its better for [debugging](#) too. We will use [emacs](#) as an example in the following.

If you’ve never used [emacs](#) before, it still might be nicer, since its pretty easy to get used to the little bit of [emacs](#) that you need. (Just type “`emacs &`” at the [UNIX command line](#) to run it; if you are on a remote terminal without visual capabilities, you can use “`emacs -nw`”).

If you don’t already have a file in your [home directory](#) called “.emacs” (note the dot at the front), create one and put the following [lines](#) in it. Otherwise add the following to your existing .emacs file:

```
(autoload 'run-prolog "prolog" "Start a Prolog sub-process." t)
(autoload 'prolog-mode "prolog" "Major mode for editing Prolog programs." t)
(setq prolog-program-name "swipl"); or whatever the prolog executable name is
(add-to-list 'auto-mode-alist '("\\.pl$" . prolog-mode))
```

The file `prolog.el`, which provides `prolog-mode` should already be [installed](#) on your machine, otherwise download it at <http://turing.ubishops.ca/home/bruda/emacs-prolog/>

Now, once you’re in [emacs](#), you will need to figure out what your “meta” key is. Usually its the alt key. (Type “control” key together with “h” to get help on using [emacs](#)). So you’ll need a “meta-X” command, then type “run-prolog”. In other words, type the meta key, type “x”, then there will be a little buffer at the bottom of your [emacs window](#) with “M-x”, where you type `run-prolog`³. This will start up the SWI [Prolog interpreter](#), ... et voilà!

The best thing is you can have two buffers “within” your [emacs](#) window, one where you’re editing your program and one where you’re running [Prolog](#). This makes [debugging](#) easier.

3.2.2 Knowledge Bases and Backtracking

Depth-First Search with Backtracking

▷ So far, all the examples led to direct [success](#) or to [failure](#).

([simple KB](#))

¹for “unary natural numbers”; we cannot use the [predicate](#) `nat` and the constructor function `s` here, since their meaning is predefined in [Prolog](#)

²for “unary natural numbers”.

³Type “control” key together with “h” then press “m” to get an exhaustive mode help.

▷ **Definition 3.2.1 (Prolog Search Procedure).** The Prolog interpreter employs top-down, left-right **depth first search**, concretely, **Prolog search**:

- ▷ works on the **subgoals** in left right order.
- ▷ **matches** first **query** with the **head literals** of the **clauses** in the **program** in top-down order.
- ▷ if there are no **matches**, **fail** and **backtracks** to the (chronologically) last **back-track point**.
- ▷ otherwise **backchain** on the first **match**, keep the other **matches** in mind for **backtracking** via **backtrack points**.

We say that a **goal** G **matches** a **head** H , iff we can make them equal by replacing **variables** in H with **terms**.

▷ We can force **backtracking** to compute more **answers** by typing `;`.

Note: With the Prolog search procedure detailed above, computation can easily go into **infinite loops**, even though the **knowledge base** could provide the correct answer. Consider for instance the simple **program**

```
p(X):- p(X).
p(X):- q(X).
q(X).
```

If we **query** this with `?- p(john)`, then **DFS** will go into an **infinite loop** because Prolog expands by default the first **predicate**. However, we can conclude that `p(john)` is true if we start expanding the second **predicate**.

In fact this is a necessary feature and not a **bug** for a **programming language**: we need to be able to write **non-terminating programs**, since the language would not be **Turing complete** otherwise. The argument can be sketched as follows: we have seen that for **Turing machines** the **halting problem** is **undecidable**. So if all Prolog programs were terminating, then Prolog would be weaker than **Turing machines** and thus not **Turing complete**.

We will now fortify our intuition about the Prolog search procedure by an example that extends the setup from `??` by a new choice of a vehicle that could be a car (if it had a motor).

Backtracking by Example

▷ **Example 3.2.2.** We extend `??`:

```
has_wheels(mytricycle,3).
has_wheels(myrollerblade,3).
has_wheels(mybmw,4).
has_motor(mybmw).
car(X):-has_wheels(X,3),has_motor(X). % cars sometimes have three wheels
car(X):-has_wheels(X,4),has_motor(X). % and sometimes four.
?- car(Y).
?- has_wheels(Y,3),has_motor(Y). % backtrack point 1
Y = mytricycle % backtrack point 2
?- has_motor(mytricycle).
FAIL % fails, backtrack to 2
Y = myrollerblade % backtrack point 2
?- has_motor(myrollerblade).
FAIL % fails, backtrack to 1
?- has_wheels(Y,4),has_motor(Y).
Y = mybmw
?- has_motor(mybmw).
Y=mybmw
true
```

In general, a **Prolog** rule of the form $A:-B,C$ reads as *A, if B and C*. If we want to express *A if B or C*, we have to express this two separate rules $A:-B$ and $A:-C$ and leave the choice which one to use to the search procedure.

In Example 3.2.2 we indeed have two **clauses** for the **predicate** `car/1`; one each for the cases of cars with three and four wheels. As the three-wheel case comes first in the program, it is explored first in the search process.

Recall that at every point, where the **Prolog interpreter** has the choice between two **clauses** for a **predicate**, chooses the first and leaves a **backtrack point**. In Example 3.2.2 this happens first for the **predicate** `car/1`, where we explore the case of three-wheeled cars. The **Prolog interpreter** immediately has to choose again – between the tricycle and the rollerblade, which both have three wheels. Again, it chooses the first and leaves a **backtrack point**. But as tricycles do not have motors, the **subgoal** `has_motor(mytricycle)` **fails** and the **interpreter backtracks** to the chronologically nearest **backtrack point** (the second one) and tries to fulfill `has_motor(myrollerblade)`. This **fails** again, and the next **backtrack point** is point 1 – note the stack-like organization of **backtrack points** which is in keeping with the **DFS** depth-first search strategy – which chooses the case of four-wheeled cars. This ultimately **succeeds** as before with `y=mybmw`.

3.2.3 Programming Features

We now turn to a more classical **programming** task: computing with numbers. Here we turn to our initial example: adding unary natural numbers. If we can do that, then we have to consider **Prolog** a **programming language**.

Can We Use This For Programming?

- ▷ **Question:** What about **functions**? E.g. the **addition function**?
- ▷ **Question:** We cannot define **functions**, in **Prolog**!
- ▷ **Idea (back to math):** use a three-place **predicate**.
- ▷ **Example 3.2.3.** `add(X,Y,Z)` stands for $X+Y=Z$
- ▷ Now we can directly write the **recursive** equations $X + 0 = X$ (**base case**) and $X + s(Y) = s(X + Y)$ into the **knowledge base**.

```
add(X,zero,X).
add(X,s(Y),s(Z)) :- add(X,Y,Z).
```
- ▷ Similarly with **multiplication** and **exponentiation**.

```
mult(X,zero,zero).
mult(X,s(Y),Z) :- mult(X,Y,W), add(X,W,Z).

expt(X,zero,s(zero)).
expt(X,s(Y),Z) :- expt(X,Y,W), mult(X,W,Z).
```

Note: Viewed through the right glasses **logic programming** is very similar to **functional programming**; the only difference is that we are using $n + 1$ **ary relations** rather than n **ary function**. To see how this works let us consider the addition function/relation example above: instead of a binary function $+$ we program a ternary relation `add`, where relation `add(X,Y,Z)` means $X + Y = Z$. We start with the same defining equations for addition, rewriting them to relational style.

The first equation is straight-forward via our correspondence and we get the **Prolog fact** `add(X,zero,X)`. For the equation $X + s(Y) = s(X + Y)$ we have to work harder, the straight-forward relational translation `add(X,s(Y),s(X+Y))` is impossible, since we have only partially replaced the function `+` with the relation `add`. Here we take refuge in a very simple trick that we can always do in logic (and **mathematics** of course): we introduce a new name `Z` for the offending expression $X + Y$ (using a variable) so that we get the **fact** `add(X,s(Y),s(Z))`. Of course this is not universally true (remember that this fact would say that “ $X + s(Y) = s(Z)$ for all X, Y , and Z ”), so we have to extend it to a **Prolog rule** `add(X,s(Y),s(Z)):-add(X,Y,Z)`. which relativizes to mean “ $X + s(Y) = s(Z)$ for all X, Y , and Z with $X + Y = Z$ ”.

Indeed the rule **implements addition** as a **recursive predicate**, we can see that the recursion relation is terminating, since the left hand sides have one more constructor for the successor function. The examples for **multiplication** and **exponentiation** can be developed analogously, but we have to use the naming trick twice.

We now apply the same principle of **recursive programming** with **predicates** to other examples to reinforce our intuitions about the principles.

More Examples from elementary Arithmetic

- ▷ **Example 3.2.4.** We can also use the `add` relation for subtraction without changing the **implementation**. We just use **variables** in the “input positions” and ground **terms** in the other two. (possibly very inefficient “generate and test approach”)

```
?-add(s(zero),X,s(s(s(zero)))).  
X = s(s(zero))  
true
```

- ▷ **Example 3.2.5.** Computing the n^{th} **Fibonacci number** (0, 1, 1, 2, 3, 5, 8, 13, ...; add the last two to get the next), using the **addition predicate** above.

```
fib(zero,zero).  
fib(s(zero),s(zero)).  
fib(s(s(X)),Y):-fib(s(X),Z),fib(X,W),add(Z,W,Y).
```

- ▷ **Example 3.2.6.** Using **Prolog’s internal arithmetic**: a goal of the form `?- D is e.` — where e is a **ground arithmetic expression** binds D to the result of evaluating e .

```
fib(0,0).  
fib(1,1).  
fib(X,Y):- D is X - 1, E is X - 2,fib(D,Z),fib(E,W), Y is Z + W.
```

Note: Note that the **is** relation does not allow “generate and test” inversion as it insists on the right hand being ground. In our example above, this is not a problem, if we call the `fib` with the first (“input”) argument a ground term. Indeed, it **matches** the last rule with a goal `?- g,Y.`, where g is a ground term, then $g-1$ and $g-2$ are ground and thus D and E are bound to the (ground) result terms. This makes the input arguments in the two **recursive calls** ground, and we get ground results for Z and W , which allows the last goal to succeed with a ground result for Y . Note as well that re-ordering the **body’s literal** of the rule so that the **recursive calls** are called before the computation **literals** will lead to **failure**.

We will now add the primitive **data structure** of lists to **Prolog**; they are constructed by prepending an element (the head) to an existing list (which becomes the rest list or “tail” of the constructed one).

Adding Lists to Prolog

- ▷ Lists are represented by **terms** of the form `[a,b,c,...]`
- ▷ **First/rest** representation `[F|R]`, where R is a **rest list**.
- ▷ **predicates** for **member**, **append** and **reverse** of **lists** in default **Prolog** representation.

```
member(X,[X|_]).
member(X,[_|R]):-member(X,R).
```

```
append([],L,L).
append([X|R],L,[X|S]):-append(R,L,S).
```

```
reverse([],[]).
reverse([X|R],L):-reverse(R,S),append(S,[X],L).
```

Just as in **functional programming** languages, we can define **list** operations by **recursion**, only that we program with **relations** instead of with **functions**.

Logic programming is the third large **programming paradigm** (together with **functional programming** and **imperative programming**).

Relational Programming Techniques

- ▷ **Example 3.2.7.** Parameters have no unique direction “in” or “out”

```
?- rev(L,[1,2,3]).
?- rev([1,2,3],L1).
?- rev([1|X],[2|Y]).
```

- ▷ **Example 3.2.8.** Symbolic programming by structural induction

```
rev([],[]).
rev([X|Xs],Ys) :- ...
```

- ▷ **Example 3.2.9.** **Generate and test:**

```
sort(Xs,Ys) :- perm(Xs,Ys), ordered(Ys).
```

From a **programming** practice point of view it is probably best understood as “relational programming” in analogy to **functional programming**, with which it shares a focus on **recursion**.

The major difference to **functional programming** is that “relational programming” does not have a fixed input/output distinction, which makes the control flow in **functional programs** very direct and predictable. Thanks to the underlying search procedure, we can sometime make use of the flexibility afforded by **logic programming**.

If the problem solution involves search (and **depth first search** is sufficient), we can just get by with specifying the problem and letting the **Prolog interpreter** do the rest. In Example 3.2.9 we just specify that list Xs can be sorted into Ys, iff Ys is a permutation of Xs and Ys is ordered. Given a concrete (input) list Xs, the **Prolog interpreter** will generate all permutations of Ys of Xs via the **predicate** `perm/2` and then test them whether they are ordered.

This is a paradigmatic example of **logic programming**. We can (sometimes) directly use the specification of a problem as a **program**. This makes the argument for the correctness of the **program** immediate, but may make the **program** execution non optimal.

3.2.4 Advanced Relational Programming

It is easy to see that the **running time** of the **Prolog** program from Example 3.2.9 is not $\mathcal{O}(n \log_2(n))$ which is optimal for sorting **algorithms**. This is the flip side of the flexibility in **logic programming**. But **Prolog** has ways of dealing with that: the **cut operator**, which is a **Prolog** atom, which always **succeeds**, but which cannot be **backtracked** over. This can be used to **prune** the **search tree** in **Prolog**. We will not go into that here but refer the readers to the literature.

Specifying Control in Prolog

- ▷ **Remark 3.2.10.** The **running time** of the program from Example 3.2.9 is not $\mathcal{O}(n \log_2(n))$ which is optimal for sorting **algorithms**.

```
sort(Xs,Ys) :- perm(Xs,Ys), ordered(Ys).
```

- ▷ **Idea:** Gain computational **efficiency** by shaping the search!

Functions and Predicates in Prolog

- ▷ **Remark 3.2.11.** **Functions** and **predicates** have radically different roles in **Prolog**.

- ▷ **Functions** are used to represent data. (e.g. `father(john)` or `s(s(zero))`)
- ▷ **Predicates** are used for stating properties about and computing with data.

- ▷ **Remark 3.2.12.** In **functional programming**, **functions** are used for both.
(even more confusing than in **Prolog** if you think about it)

- ▷ **Example 3.2.13.** Consider again the reverse program for lists below:

An input datum is e.g. [1,2,3], then the output datum is [3,2,1].

```
reverse([], []).
reverse([X|R],L):-reverse(R,S),append(S,[X],L).
```

We “define” the computational behavior of the **predicate** `rev`, but the list constructors `[. . .]` are just used to construct lists from arguments.

- ▷ **Example 3.2.14 (Trees and Leaf Counting).** We represent (unlabelled) trees via the function `t` from tree lists to trees. For instance, a **balanced binary tree** of depth 2 is `t([t([t([],t([]))],t([t([],t([]))]))])`. We count leaves by

```
leafcount(t([],),1).
leafcount(t([X|R]),Y) :- leafcount(X,Z), leafcount(t(R,W)), Y is Z + W.
```

For more information on Prolog

RTFM ($\hat{=}$ “read the fine manuals”)

- ▷ **RTFM Resources:** There are also lots of good tutorials on the web,
 - ▷ I personally like [Fis; LPN],
 - ▷ [Fla94] has a very thorough logic-based introduction,
 - ▷ consult also the SWI Prolog Manual [SWI],

Chapter 4

Recap of Prerequisites from Math & Theoretical Computer Science

In this chapter we will briefly recap some of the prerequisites from theoretical [computer science](#) that are needed for understanding Artificial Intelligence 1.

4.1 Recap: Complexity Analysis in AI?

We now come to an important topic which is not really part of [Artificial Intelligence](#) but which adds an important layer of understanding to this enterprise: We (still) live in the era of Moore's law (the computing power available on a single [CPU](#) doubles roughly every two years) leading to an exponential increase. A similar rule holds for main memory and disk storage capacities. And the production of [computer](#) (using [CPUs](#) and [memory](#)) is (still) very rapidly growing as well; giving mankind as a whole, institutions, and individual exponentially grow of computational resources.

In public discussion, this development is often cited as the reason why (strong) [AI](#) is inevitable. But the argument is fallacious if all the [algorithms](#) we have are of very high complexity (i.e. at least [exponential](#) in either [time](#) or [space](#)). So, to judge the state of play in [Artificial Intelligence](#), we have to know the complexity of our [algorithms](#).

In this section, we will give a very brief recap of some aspects of elementary [complexity theory](#) and make a case of why this is a generally important for [computer scientists](#).

[A Video Nugget](#) covering this section can be found at <https://fau.tv/clip/id/21839> and <https://fau.tv/clip/id/21840>.

To get a feeling what we mean by “fast [algorithm](#)”, we do some preliminary computations.

Performance and Scaling

- ▷ Suppose we have three [algorithms](#) to choose from. (which one to select)
- ▷ Systematic analysis reveals performance characteristics.
- ▷ **Example 4.1.1.** For a problem of size n we have

size	performance		
	linear	quadratic	exponential
n	$100n\mu s$	$7n^2\mu s$	$2^n\mu s$
1	$100\mu s$	$7\mu s$	$2\mu s$
5	$.5ms$	$175\mu s$	$32\mu s$
10	$1ms$	$.7ms$	$1ms$
45	$4.5ms$	$14ms$	$1.1Y$
100
1 000
10 000
1 000 000

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG

Michael Kohlhase: Artificial Intelligence 1 59 2024-02-08

What?! One year?

- ▷ $2^{10} = 1024$ ($1024\mu s \simeq 1ms$)
- ▷ $2^{45} = 35\,184\,372\,088\,832$ ($3.5 \times 10^{13}\mu s \simeq 3.5 \times 10^7 s \simeq 1.1Y$)
- ▷ **Example 4.1.2.** we denote all times that are longer than the age of the universe with –

size	performance		
	linear	quadratic	exponential
n	$100n\mu s$	$7n^2\mu s$	$2^n\mu s$
1	$100\mu s$	$7\mu s$	$2\mu s$
5	$.5ms$	$175\mu s$	$32\mu s$
10	$1ms$	$.7ms$	$1ms$
45	$4.5ms$	$14ms$	$1.1Y$
< 100	$100ms$	$7s$	$10^{16}Y$
1 000	$1s$	$12min$	–
10 000	$10s$	$20h$	–
1 000 000	$1.6min$	$2.5mon$	–

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG

Michael Kohlhase: Artificial Intelligence 1 60 2024-02-08

So it does make a difference for larger problems what **algorithm** we choose. Considerations like the one we have shown above are very important when judging an **algorithm**. These evaluations go by the name of “**complexity theory**”.

Let us now recapitulate some notions of elementary **complexity theory**: we are interested in the worst case growth of the resources (**time** and **space**) required by an **algorithm** in terms of the sizes of its arguments. **Mathematically** we look at the **functions** from input size to resource size and classify them into “big-O” classes, abstracting from constant **factors** (which depend on the machine the **algorithm** runs on and which we cannot control) and initial (**algorithm** startup) factors.

Recap: Time/Space Complexity of Algorithms

- ▷ We are mostly interested in worst-case **complexity** in AI-1.
- ▷ **Definition:** Let $S \subseteq \mathbb{N} \rightarrow \mathbb{N}$ be a set of **natural number functions**, then we say that an **algorithm** α that terminates in time $t(n)$ for all **inputs** of **size** n has **running**

time $T(\alpha) := t$.

We say that α has **time complexity** in S (written $T(\alpha) \in S$ or colloquially $T(\alpha) = S$), iff $t \in S$. We say α has **space complexity** in S , iff α uses only memory of size $s(n)$ on inputs of size n and $s \in S$.

▷ **Time/space complexity** depends on size measures. (no canonical one)

▷ **Definition:** The following sets are often used for S in $T(\alpha)$:

Landau set	class name	rank	Landau set	class name	rank
$\mathcal{O}(1)$	constant	1	$\mathcal{O}(n^2)$	quadratic	4
$\mathcal{O}(\ln(n))$	logarithmic	2	$\mathcal{O}(n^k)$	polynomial	5
$\mathcal{O}(n)$	linear	3	$\mathcal{O}(k^n)$	exponential	6

where $\mathcal{O}(g) = \{f | \exists k > 0. f \leq_a k \cdot g\}$ and $f \leq_a g$ (f is asymptotically bounded by g), iff there is an $n_0 \in \mathbb{N}$, such that $f(n) \leq g(n)$ for all $n > n_0$.

▷ For $k' > 2$ and $k > 1$ we have $\mathcal{O}(1) \subset \mathcal{O}(\log n) \subset \mathcal{O}(n) \subset \mathcal{O}(n^2) \subset \mathcal{O}(n^{k'}) \subset \mathcal{O}(k^n)$

▷ **For AI-1:** I expect that given an algorithm, you can determine its complexity class. (next)

OK, that was the theory, ... but how do we use that in practice.

Determining the Time/Space Complexity of Algorithms

▷ **Definition 4.1.3.** Given a function Γ that maps variables v to sets $\Gamma(v)$, we compute $T_\Gamma(\alpha)$ and $C_\Gamma(\alpha)$ of an imperative algorithm α by induction on the structure of α :

▷ **constant:** can be accessed in constant time. If $\alpha = \delta$ for a data constant δ , then $T_\Gamma(\alpha) \in \mathcal{O}(1)$.

▷ **variable:** need the complexity of the value
If $\alpha = v$ with $v \in \text{dom}(\Gamma)$, then $T_\Gamma(\alpha) \in \mathcal{O}(\Gamma(v))$.

▷ **application:** compose the complexities of the function and the argument
If $\alpha = \varphi(\psi)$ with $T_\Gamma(\varphi) \in \mathcal{O}(f)$ and $T_{\Gamma \cup C_\Gamma(\varphi)}(\psi) \in \mathcal{O}(g)$, then $T_\Gamma(\alpha) \in \mathcal{O}(f \circ g)$ and $C_\Gamma(\alpha) = C_{\Gamma \cup C_\Gamma(\varphi)}(\psi)$.

▷ **assignment:** has to compute the value \rightsquigarrow has its complexity
If α is $v := \varphi$ with $T_\Gamma(\varphi) \in S$, then $T_\Gamma(\alpha) \in S$ and $C_\Gamma(\alpha) = \Gamma \cup (v, S)$.

▷ **composition:** has the maximal complexity of the components
If α is $\varphi; \psi$, with $T_\Gamma(\varphi) \in P$ and $T_{\Gamma \cup C_\Gamma(\varphi)}(\psi) \in Q$, then $T_\Gamma(\alpha) \in \max\{P, Q\}$ and $C_\Gamma(\alpha) = C_{\Gamma \cup C_\Gamma(\varphi)}(\psi)$.

▷ **branching:** has the maximal complexity of the condition and branches
If α is **if γ then φ else ψ end**, with $T_\Gamma(\gamma) \in C$, $T_{\Gamma \cup C_\Gamma(\gamma)}(\varphi) \in P$, $T_{\Gamma \cup C_\Gamma(\gamma)}(\psi) \in Q$, and then $T_\Gamma(\alpha) \in \max\{C, P, Q\}$ and $C_\Gamma(\alpha) = \Gamma \cup C_\Gamma(\gamma) \cup C_{\Gamma \cup C_\Gamma(\gamma)}(\varphi) \cup C_{\Gamma \cup C_\Gamma(\gamma)}(\psi)$.

▷ **looping:** multiplies complexities
If α is **while γ do φ end**, with $T_\Gamma(\gamma) \in \mathcal{O}(f)$, $T_{\Gamma \cup C_\Gamma(\gamma)}(\varphi) \in \mathcal{O}(g)$, then $T_\Gamma(\alpha) \in \mathcal{O}(f(n) \cdot g(n))$ and $C_\Gamma(\alpha) = C_{\Gamma \cup C_\Gamma(\gamma)}(\varphi)$.

▷ The time complexity $T(\alpha)$ is just $T_{\emptyset}(\alpha)$, where \emptyset is the empty function.

▷ Recursion is much more difficult to analyze \leadsto recurrence relations and Master's theorem.

Please excuse the chemistry pictures, public imagery for CS is really just quite boring, this is what people think of when they say “scientist”. So, imagine that instead of a chemist in a lab, it's me sitting in front of a computer.

Why Complexity Analysis? (General)

▷ **Example 4.1.4.** Once upon a time I was trying to invent an efficient algorithm.

▷ My first algorithm attempt didn't work, so I had to try harder.

▷ But my 2nd attempt didn't work either, which got me a bit agitated.

▷ The 3rd attempt didn't work either. . .

▷ And neither the 4th. But then:

▷ Ta-da ... when, for once, I turned around and looked in the other direction— CAN one actually solve this *efficiently*? – NP hardness was there to rescue me.

Why Complexity Analysis? (General)

▷ **Example 4.1.5.** Trying to find a sea route east to India (from Spain) (does not exist)

- ▷ **Observation:** Complexity theory saves you from spending lots of time trying to invent algorithms that do not exist.

It's like, you're trying to find a route to India (from Spain), and you presume it's somewhere to the east, and then you hit a coast, but no; try again, but no; try again, but no; ... if you don't have a map, that's the best you can do. But NP hardness gives you the map: you can check that there actually is no way through here. But what is this notion of NP completeness alluded to above? We observe that we can analyze the complexity of problems by the complexity of the algorithms that solve them. This gives us a notion of what to expect from solutions to a given problem class, and thus whether efficient (i.e. polynomial time) algorithms can exist at all.

Reminder (?): NP and PSPACE (details \leadsto e.g. [GJ79])

- ▷ **Turing Machine:** Works on a tape consisting of cells, across which its Read/Write head moves. The machine has internal states. There is a transition function that specifies – given the current cell content and internal state – what the subsequent internal state will be, how what the R/W head does (write a symbol and/or move). Some internal states are accepting.
- ▷ Decision problems are in NP if there is a non deterministic Turing machine that halts with an answer after time polynomial in the size of its input. Accepts if at least one of the possible runs accepts.
- ▷ Decision problems are in NPSpace, if there is a non deterministic Turing machine that runs in space polynomial in the size of its input.
- ▷ **NP vs. PSPACE:** Non-deterministic polynomial space can be simulated in deterministic polynomial space. Thus $PSPACE = NPSpace$, and hence (trivially) $NP \subseteq PSPACE$.
It is commonly believed that $NP \not\subseteq PSPACE$. (similar to $P \subseteq NP$)

The Utility of Complexity Knowledge (NP-Hardness)

- ▷ **Assume:** In 3 years from now, you have finished your studies and are working in

your first industry job. Your boss Mr. X gives you a problem and says *Solve It!*. By which he means, *write a program that solves it efficiently*.

- ▷ **Question:** Assume further that, after trying in vain for 4 weeks, you got the next meeting with Mr. X. **How could knowing about NP hardness help?**
- ▷ **Answer:** reserved for the plenary sessions \rightsquigarrow be there!

4.2 Recap: Formal Languages and Grammars

One of the main ways of designing **rational agents** in this course will be to define **formal languages** that represent the state of the **agent environment** and let the agent use various inference techniques to predict effects of its observations and **actions** to obtain a world model. In this section we recap the basics of **formal languages** and **grammars** that form the basis of a **compositional** theory for them.

The Mathematics of Strings

- ▷ **Definition 4.2.1.** An **alphabet** A is a **finite set**; we call each element $a \in A$ a **character**, and an n **tuple** $s \in A^n$ a **string** (of **length** n over A).
- ▷ **Definition 4.2.2.** Note that $A^0 = \{\langle \rangle\}$, where $\langle \rangle$ is the (unique) 0-tuple. With the definition above we consider $\langle \rangle$ as the **string of length 0** and call it the **empty string** and denote it with ϵ .
- ▷ **Note:** Sets \neq strings, e.g. $\{1, 2, 3\} = \{3, 2, 1\}$, but $\langle 1, 2, 3 \rangle \neq \langle 3, 2, 1 \rangle$.
- ▷ **Notation:** We will often write a string $\langle c_1, \dots, c_n \rangle$ as " $c_1 \dots c_n$ ", for instance "abc" for $\langle a, b, c \rangle$
- ▷ **Example 4.2.3.** Take $A = \{h, 1, / \}$ as an **alphabet**. Each of the members h , 1 , and $/$ is a **character**. The **vector** $\langle /, /, 1, h, 1 \rangle$ is a **string of length 5** over A .
- ▷ **Definition 4.2.4 (String Length).** Given a **string** s we denote its **length** with $|s|$.
- ▷ **Definition 4.2.5.** The **concatenation** $\text{conc}(s, t)$ of two **strings** $s = \langle s_1, \dots, s_n \rangle \in A^n$ and $t = \langle t_1, \dots, t_m \rangle \in A^m$ is defined as $\langle s_1, \dots, s_n, t_1, \dots, t_m \rangle \in A^{n+m}$.
We will often write $\text{conc}(s, t)$ as $s + t$ or simply st
- ▷ **Example 4.2.6.** $\text{conc}(\text{"text"}, \text{"book"}) = \text{"text"} + \text{"book"} = \text{"textbook"}$

We have multiple notations for **concatenation**, since it is such a basic operation, which is used so often that we will need very short notations for it, trusting that the reader can **disambiguate** based on the context.

Now that we have defined the concept of a **string** as a sequence of **characters**, we can go on to give ourselves a way to distinguish between good **strings** (e.g. **programs** in a given **programming language**) and bad **strings** (e.g. such with syntax errors). The way to do this by the concept of a **formal language**, which we are about to define.

Formal Languages

- ▷ **Definition 4.2.7.** Let A be an **alphabet**, then we define the **sets** $A^+ := \bigcup_{i \in \mathbb{N}^+} A^i$ of **nonempty string** and $A^* := A^+ \cup \{\epsilon\}$ of **strings**.
- ▷ **Example 4.2.8.** If $A = \{a, b, c\}$, then $A^* = \{\epsilon, a, b, c, aa, ab, ac, ba, \dots, aaa, \dots\}$.
- ▷ **Definition 4.2.9.** A **set** $L \subseteq A^*$ is called a **formal language** over A .
- ▷ **Definition 4.2.10.** We use $c^{[n]}$ for the **string** that consists of the **character** c **repeated** n times.
- ▷ **Example 4.2.11.** $\#^{[5]} = \langle \#, \#, \#, \#, \# \rangle$
- ▷ **Example 4.2.12.** The **set** $M := \{ba^{[n]} \mid n \in \mathbb{N}\}$ of **strings** that start with **character** b followed by an arbitrary numbers of a 's is a **formal language** over $A = \{a, b\}$.
- ▷ **Definition 4.2.13 (Operations on Languages).** Let $L, L_1,$ and L_2 be **formal languages** over the same **alphabet**, then we define language level operations: The **concatenation** of L_1 and L_2 ; $L_1L_2 := \{s_1s_2 \mid s_1 \in L_1 \wedge s_2 \in L_2\}$, $L^+ := \{s^+ \mid s \in L\}$, and $L^* := \{s^* \mid s \in L\}$.

There is a common **misconception** that a **formal language** is something that is difficult to understand as a concept. This is not true, the only thing a **formal language** does is separate the “good” from the bad **strings**. Thus we simply model a formal language as a set of stings: the “good” **strings** are members, and the “bad” ones are not.

Of course this definition only shifts complexity to the way we construct specific **formal languages** (where it actually belongs), and we have learned two (simple) ways of constructing them: by **repetition** of **characters**, and by **concatenation** of existing **languages**.

As mentioned above, the purpose of a **formal language** is to distinguish “good” from “bad” **strings**. It is maximally general, but not helpful, since it does not support **computation** and **inference**. In practice we will be interested in **formal languages** that have some structure, so that we can represent **formal languages** in a **finite** manner (recall that a **formal language** is a **subset** of A^* , which may be **infinite** and even **undecidable** – even though the **alphabet** A is **finite**).

To remedy this, we will now introduce **phrase structure grammars** (or just **grammars**), the standard tool for describing structured **formal languages**.

Phrase Structure Grammars (Theory)

- ▷ **Recap:** A formal language is an arbitrary set of **symbol** sequences.
- ▷ **Problem:** This may be **infinite** and even **undecidable** even if A is **finite**.
- ▷ **Idea:** Find a way of representing **formal languages** with structure **finitely**.
- ▷ **Definition 4.2.14.** A **phrase structure grammar** (or just **grammar**) is a tuple $\langle N, \Sigma, P, S \rangle$ where
 - ▷ N is a **finite set** of **nonterminal symbols**,
 - ▷ Σ is a **finite set** of **terminal symbols**, members of $\Sigma \cup N$ are called **symbols**.
 - ▷ P is a **finite set** of **production rules**: pairs $p := h \rightarrow b$ (also written as $h \Rightarrow b$), where $h \in (\Sigma \cup N)^* N (\Sigma \cup N)^*$ and $b \in (\Sigma \cup N)^*$. The **string** h is called the **head** of p and b the **body**.
 - ▷ $S \in N$ is a distinguished **symbol** called the **start symbol** (also **sentence symbol**).

- ▷ **Intuition:** Production rules map strings with at least one nonterminal to arbitrary other strings.
- ▷ **Notation:** If we have n rules $h \rightarrow b_i$ sharing a head, we often write $h \rightarrow b_1 \mid \dots \mid b_n$ instead.

We fortify our intuition about these – admittedly very abstract – constructions by an example and introduce some more vocabulary.

Phrase Structure Grammars (cont.)

- ▷ **Example 4.2.15.** A simple phrase structure grammar G :

$$\begin{aligned} S &\rightarrow NP Vi \\ NP &\rightarrow Article N \\ Article &\rightarrow \mathbf{the} \mid \mathbf{a} \mid \mathbf{an} \\ N &\rightarrow \mathbf{dog} \mid \mathbf{teacher} \mid \dots \\ Vi &\rightarrow \mathbf{sleeps} \mid \mathbf{smells} \mid \dots \end{aligned}$$

Here S , is the start symbol, NP , VP , $Article$, N , and Vi are nonterminals.

- ▷ **Definition 4.2.16.** The subset of lexical rules, i.e. those whose body consists of a single terminal is called its lexicon and the set of body symbols the vocabulary (or alphabet). The nonterminals in their heads are called lexical categories.
- ▷ **Definition 4.2.17.** The non-lexicon production rules are called structural, and the nonterminals in the heads are called phrasal categories.

Now we look at just how a grammar helps in analyzing formal languages. The basic idea is that a grammar accepts a word, iff the start symbol can be rewritten into it using only the rules of the grammar.

Phrase Structure Grammars (Theory)

- ▷ **Idea:** Each symbol sequence in a formal language* can be analyzed/generated by the grammar.
- ▷ **Definition 4.2.18.** Given a phrase structure grammar $G := \langle N, \Sigma, P, S \rangle$, we say G derives $t \in (\Sigma \cup N)^*$ from $s \in (\Sigma \cup N)^*$ in one step, iff there is a production rule $p \in P$ with $p = h \rightarrow b$ and there are $u, v \in (\Sigma \cup N)^*$, such that $s = suhv$ and $t = ubv$. We write $s \xrightarrow{p}_G t$ (or $s \rightarrow_G t$ if p is clear from the context) and use \rightarrow_G^* for the reflexive transitive closure of \rightarrow_G . We call $s \rightarrow_G^* t$ a G derivation of t from s .
- ▷ **Definition 4.2.19.** Given a phrase structure grammar $G := \langle N, \Sigma, P, S \rangle$, we say that $s \in (N \cup \Sigma)^*$ is a sentential form of G , iff $S \rightarrow_G^* s$. A sentential form that does not contain nonterminals is called a sentence of G , we also say that G accepts s .
- ▷ **Definition 4.2.20.** The language $L(G)$ of G is the set of its sentences.

Definition 4.2.21. We call two **grammars equivalent**, iff they have the same **languages**.

- ▷ **Definition 4.2.22.** **Parsing, syntax analysis, or syntactic analysis** is the process of analyzing a **string of symbols**, either in a **formal** or a **natural language** by means of a **grammar**.

Phrase Structure Grammars (Example)

- ▷ **Example 4.2.23.** In the **grammar G** from Example 4.2.15:

1. **Article teacher V_i** is a **sentential form**,

$$\begin{aligned} S &\rightarrow_G NP V_i \\ &\rightarrow_G Article N V_i \\ &\rightarrow_G Article \mathbf{teacher} V_i \end{aligned}$$

2. **The teacher sleeps** is a **sentence**.

$$\begin{aligned} S &\rightarrow_G^* Article \mathbf{teacher} V_i \\ &\rightarrow_G \mathbf{the teacher} V_i \\ &\rightarrow_G \mathbf{the teacher sleeps} \end{aligned}$$

$$\begin{aligned} S &\rightarrow NP V_i \\ NP &\rightarrow Article N \\ Article &\rightarrow \mathbf{the} \mid \mathbf{a} \mid \mathbf{an} \mid \dots \\ N &\rightarrow \mathbf{dog} \mid \mathbf{teacher} \mid \dots \\ V_i &\rightarrow \mathbf{sleeps} \mid \mathbf{smells} \mid \dots \end{aligned}$$

Note that this process indeed defines a **formal language** given a **grammar**, but does not provide an **efficient algorithm** for **parsing**, even for the simpler kinds of **grammars** we introduce below.

Grammar Types (Chomsky Hierarchy [Cho65])

- ▷ **Observation:** The shape of the **grammar** determines the “size” of its **language**.

- ▷ **Definition 4.2.24.** We call a **grammar** and the **formal language** it accepts:

1. **context-sensitive**, if the **bodies** of **production rules** have no less **symbols** than the **heads**,
2. **context-free**, if the **heads** have exactly one **symbol**,
3. **regular**, if additionally, **bodies** is **empty** or consists of a **nonterminal**, optionally followed by a **terminal symbol**.

By extension, a **formal language L** is called **context-sensitive/context-free/regular**, iff it is the **language** of a respective **grammar**. **Context-free grammars** are sometimes **CFLs** and **context-free languages CFGs**.

- ▷ **Example 4.2.25 (Languages and their Grammars).**

- ▷ Context-sensitive: The language $\{a^{[n]}b^{[n]}c^{[n]}\}$ is accepted by

$$\begin{aligned} S &\rightarrow \mathbf{a b c} \mid A \\ A &\rightarrow \mathbf{a} A B \mathbf{c} \mid \mathbf{a b c} \\ c B &\rightarrow B \mathbf{c} \\ b B &\rightarrow \mathbf{b b} \end{aligned}$$

- ▷ Context-free: The language $\{a^{[n]}b^{[n]}\}$ is accepted by $S \rightarrow \mathbf{a} S \mathbf{b} \mid \epsilon$.
- ▷ Regular: The language $\{a^{[n]}\}$ is accepted by $S \rightarrow S \mathbf{a}$
- ▷ **Observation:** Natural languages are probably context-sensitive but parsable in real time! (like languages low in the hierarchy)

Useful Extensions of Phrase Structure Grammars

- ▷ **Definition 4.2.26.** The **Bachus Naur form** or **Backus normal form** (BNF) is a metasyntax notation for context-free grammars.

It extends the body of a production rule by multiple (admissible) constructors:

- ▷ alternative: $s_1 \mid \dots \mid s_n$,
- ▷ repetition: s^* (arbitrary many s) and s^+ (at least one s),
- ▷ optional: $[s]$ (zero or one times), and
- ▷ grouping: $(s_1 ; \dots ; s_n)$, useful e.g. for repetition.
- ▷ **Observation:** All of these can be eliminated, .e.g. (\leadsto many more rules)
 - ▷ replace $X \rightarrow Z (s^*) W$ with the production rules $X \rightarrow Z Y W$, $Y \rightarrow \epsilon$, and $Y \rightarrow Y s$.
 - ▷ replace $X \rightarrow Z (s^+) W$ with the production rules $X \rightarrow Z Y W$, $Y \rightarrow s$, and $Y \rightarrow Y s$.

An Grammar Notation for AI-1

- ▷ **Problem:** In grammars, notations for nonterminal symbols should be
 - ▷ short and mnemonic (for the use in the body)
 - ▷ close to the official name of the syntactic category (for the use in the head)
- ▷ In AI-1 we will only use context-free grammars (simpler, but problem still applies)
- ▷ **in AI-1:** I will try to give "grammar overviews" that combine those, e.g. the grammar of first-order logic.

variables	X	\in	\mathcal{V}_1	
function constants	f^k	\in	Σ_k^f	
predicate constants	p^k	\in	Σ_k^p	
terms	t	$::=$	X	variable
			f^0	constant
			$f^k(t_1, \dots, t_k)$	application
formulae	A	$::=$	$p^k(t_1, \dots, t_k)$	atomic
			$\neg A$	negation
			$A_1 \wedge A_2$	conjunction
			$\forall X.A$	quantifier

 Michael Kohlhase: Artificial Intelligence 1
 75 2024-02-08 

We will generally get by with [context-free grammars](#), which have highly [efficient](#) [parsing algorithms](#), for the [formal language](#) we use in this course, but we will not cover the [algorithms](#) in AI-1.

4.3 Mathematical Language Recap

Mathematical Structures

- ▷ **Observation:** Mathematicians often cast object classes as [mathematical structures](#).
- ▷ We have just seen this: repeated here for convenience.
- ▷ **Definition 4.3.1.** A [phrase structure grammar](#) (or just [grammar](#)) is a tuple $\langle N, \Sigma, P, S \rangle$ where
 - ▷ N is a [finite set](#) of [nonterminal symbols](#),
 - ▷ Σ is a [finite set](#) of [terminal symbols](#), members of $\Sigma \cup N$ are called [symbols](#).
 - ▷ P is a [finite set](#) of [production rules](#): pairs $p := h \rightarrow b$ (also written as $h \Rightarrow b$), where $h \in (\Sigma \cup N)^* N (\Sigma \cup N)^*$ and $b \in (\Sigma \cup N)^*$. The [string](#) h is called the [head](#) of p and b the [body](#).
 - ▷ $S \in N$ is a distinguished [symbol](#) called the [start symbol](#) (also [sentence symbol](#)).
- ▷ **Observation:** Even though we call [production rules](#) “pairs” above, they are also [mathematical structures](#) $\langle h, b \rangle$ with a funny notation $h \rightarrow b$.

Mathematical Structures in Programming

- ▷ Most [programming languages](#) have some way of creating “named structures”. Referencing [components](#) is usually done via “dot notation”

- ▷ **Example 4.3.2 (Structs in C).**

```
// Create structures grule grammar
struct grule {
```

```

char[] head;
char[] body;
}

struct grammar {
    char[] nterminals;
    char[] termininals;
    grule[] grules;
    char[] start;
}

int main() {
    struct grule r1;
    r1.head = "foo";
    r1.body = "bar";
}
    
```

In AI-1 we use a mixture between Math and Programming Styles

- ▷ In AI-1 we use **mathematical** notation, ...
- ▷ **Definition 4.3.3.** A **structure signature** combines the components, their “types”, and **accessor** names of a **mathematical structure** in a tabular overview.

▷ **Example 4.3.4.**

$$\text{grammar} = \left\langle \begin{array}{ll} N & \text{Set} \\ \Sigma & \text{Set} \\ P & \{h \rightarrow b \mid \dots\} \\ S & N \end{array} \begin{array}{l} \text{nonterminal symbols,} \\ \text{terminal symbols,} \\ \text{productionrules,} \\ \text{start symbol} \end{array} \right\rangle$$

$$\text{grule } h \rightarrow b = \left\langle \begin{array}{ll} h & (\Sigma \cup N)^*, N, (\Sigma \cup N)^* \\ b & (\Sigma \cup N)^* \end{array} \begin{array}{l} \text{head,} \\ \text{body} \end{array} \right\rangle$$

Read N **Set nonterminal symbols** as “ N is in set and is a **nonterminal symbol**”. Here – and in the future – we will use **Set** for the **class of sets** \rightsquigarrow “ N is a **set**”.

- ▷ I will try to give **structure signatures** where necessary.

Chapter 5

Rational Agents: a Unifying Framework for Artificial Intelligence

In this chapter, we introduce a framework that gives a comprehensive conceptual model for the multitude of methods and [algorithms](#) we cover in this course. The framework of [rational agents](#) accommodates two traditions of [AI](#).

Initially, the focus of AI research was on [symbolic methods](#) concentrating on the mental processes of problem solving, starting from Newell/Simon’s “physical symbol hypothesis”:

A physical symbol system has the necessary and sufficient means for general intelligent action.
[NS76]

Here a [symbol](#) is a representation an idea, object, or relationship that is physically manifested in (the brain of) an intelligent agent (human or artificial).

Later – in the 1980s – the proponents of [embodied AI](#) posited that most features of cognition, whether human or otherwise, are shaped – or at least critically influenced – by aspects of the entire body of the organism. The aspects of the body include the motor system, the perceptual system, bodily interactions with the environment (situatedness) and the assumptions about the world that are built into the structure of the organism. They argue that [symbols](#) are not always necessary since

The world is its own best model. It is always exactly up to date. It always has every detail there is to be known. The trick is to sense it appropriately and often enough. [Bro90]

The framework of [rational agents](#) initially introduced by Russell and Wefald in [RW91] – accommodates both, it situates agents with [percepts](#) and [actions](#) in an [environment](#), but does not preclude physical symbol systems – i.e. systems that manipulate [symbols](#) as [agent functions](#). Russell and Norvig make it the central metaphor of their book “Artificial Intelligence – A modern approach” [RN03], which we follow in this course.

5.1 Introduction: Rationality in Artificial Intelligence

We now introduce the notion of [rational agents](#) as entities in the world that act optimally (given the available information). We situate [rational agents](#) in the scientific landscape by looking at variations of the concept that lead to slightly different fields of study.

What is AI? Going into Details

▷ **Recap:** AI studies how we can make the [computer](#) do things that [humans](#) can still [do better](#) at the moment. (humans are proud to be rational)

- ▷ **What is AI?:** Four possible answers/facets: Systems that

think like humans	think rationally
act like humans	act rationally

expressed by four different definitions/quotes:

	Humanly	Rational
Thinking	<i>“The exciting new effort to make computers think ... machines with human-like minds”</i> [Hau85]	<i>“The formalization of mental faculties in terms of computational models”</i> [CM85]
Acting	<i>“The art of creating machines that perform actions requiring intelligence when performed by people”</i> [Kur90]	<i>“The branch of CS concerned with the automation of appropriate behavior in complex situations”</i> [LS93]

- ▷ **Idea:** Rationality is performance-oriented rather than based on imitation.

So, what does modern AI do?

- ▷ **Acting Humanly:** Turing test, not much pursued outside Loebner prize
- ▷ $\hat{=}$ building pigeons that can fly so much like real pigeons that they can fool pigeons
 - ▷ Not reproducible, not amenable to **mathematical** analysis
- ▷ **Thinking Humanly:** \rightsquigarrow Cognitive Science.
- ▷ How do humans think? How does the (human) brain work?
 - ▷ Neural networks are a (extremely simple so far) approximation
- ▷ **Thinking Rationally:** Logics, Formalization of knowledge and inference
- ▷ You know the basics, we do some more, fairly widespread in modern **AI**
- ▷ **Acting Rationally:** How to make good action choices?
- ▷ Contains logics (one possible way to make intelligent decisions)
 - ▷ We are interested in making good choices in practice (e.g. in AlphaGo)

We now discuss all of the four facets in a bit more detail, as they all either contribute directly to our discussion of **AI** methods or characterize neighboring disciplines.

Acting humanly: The Turing test

- ▷ Introduced by Alan Turing (1950) “Computing machinery and intelligence” [Tur50]:

- ▷ “Can machines think?” → “Can machines behave intelligently?”
- ▷ **Definition 5.1.1.** The **Turing test** is an operational test for intelligent behavior based on an **imitation game** over teletext (arbitrary topic)

- ▷ It was predicted that by 2000, a machine might have a 30% chance of fooling a lay person for 5 minutes.
- ▷ **Note:** In [Tur50], Alan Turing
 - ▷ anticipated all major arguments against AI in following 50 years and
 - ▷ suggested major components of AI: knowledge, reasoning, language understanding, learning
- ▷ **Problem:** Turing test is not **reproducible**, **constructive**, or amenable to **mathematical** analysis!

Thinking humanly: Cognitive Science

- ▷ **1960s:** “**cognitive revolution**”: information processing psychology replaced prevailing orthodoxy of **behaviorism**.
- ▷ Requires scientific theories of internal activities of the brain
- ▷ What level of abstraction? “**Knowledge**” or “**circuits**”?
- ▷ **How to validate?:** Requires
 1. Predicting and testing behavior of human subjects or (top-down)
 2. Direct identification from neurological data. (bottom-up)
- ▷ **Definition 5.1.2.** **Cognitive Science** is the interdisciplinary, scientific study of the mind and its processes. It examines the nature, the tasks, and the functions of cognition.
- ▷ **Definition 5.1.3.** **Cognitive Neuroscience** studies the biological processes and aspects that underlie cognition, with a specific focus on the neural connections in the brain which are involved in mental processes.
- ▷ Both approaches/disciplines are now distinct from AI.
- ▷ Both share with AI the following characteristic: *the available theories do not explain (or engender) anything resembling human-level general intelligence*
- ▷ Hence, all three fields share one principal direction!

Thinking rationally: Laws of Thought

- ▷ **Normative** (or **prescriptive**) rather than **descriptive**
- ▷ Aristotle: what are correct arguments/thought processes?
- ▷ Several Greek schools developed various forms of **logic**: *notation* and *rules of derivation* for thoughts; may or may not have proceeded to the idea of mechanization.
- ▷ Direct line through **mathematics** and philosophy to modern **AI**
- ▷ **Problems:**
 1. Not all intelligent behavior is mediated by logical deliberation
 2. **What is the purpose of thinking?** What thoughts *should* I have out of all the thoughts (logical or otherwise) that I *could* have?

Acting Rationally

- ▷ **Idea:** Rational behavior $\hat{=}$ doing the right thing!
- ▷ **Definition 5.1.4.** **Rational behavior** consists of always doing what is **expected** to **maximize** goal achievement given the available information.
- ▷ **Rational behavior** does not necessarily involve thinking e.g., blinking reflex — but thinking should be in the service of rational action.
- ▷ **Aristotle:** *Every art and every inquiry, and similarly every action and pursuit, is thought to aim at some good.* (Nicomachean Ethics)

The Rational Agents

- ▷ **Definition 5.1.5.** An **agent** is an entity that **perceives** and **acts**.
- ▷ **Central Idea:** This course is about designing **agent** that exhibit **rational behavior**, i.e. for any given class of **environments** and tasks, we seek the **agent** (or class of **agents**) with the best performance.
- ▷ **Caveat:** *Computational limitations make perfect rationality unachievable*
 \leadsto design best **program** for given machine resources.

5.2 Agents and Environments as a Framework for AI

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/21843>.

Agents and Environments

- ▷ **Definition 5.2.1.** An **agent** is anything that
 - ▷ **perceives** its **environment** via **sensors** (a means of sensing the **environment**)
 - ▷ **acts** on it with **actuators** (means of changing the **environment**).

- ▷ **Example 5.2.2.** **Agents** include humans, robots, softbots, thermostats, etc.

Modeling Agents Mathematically and Computationally

- ▷ **Definition 5.2.3.** A **percept** is the **perceptual input** of an **agent** at a specific time instant.
- ▷ **Definition 5.2.4.** Any recognizable, coherent employment of the **actuators** of an **agent** is called an **action**.
- ▷ **Definition 5.2.5.** The **agent function** f_a of an **agent** a maps from **percept** histories to **actions**:

$$f_a: \mathcal{P}^* \rightarrow \mathcal{A}$$

- ▷ We assume that **agents** can always **perceive** their own **actions**. (but not necessarily their consequences)
- ▷ **Problem:** **agent functions** can become very big (theoretical tool only)
- ▷ **Definition 5.2.6.** An **agent function** can be **implemented** by an **agent program** that runs on a physical **agent architecture**.

Agent Schema: Visualizing the Internal Agent Structure

- ▷ **Agent Schema:** We will use the following kind of **agent schema** to visualize the

internal structure of an **agent**:

Different **agents** differ on the contents of the white box in the center.

Example: Vacuum-Cleaner World and Agent

▷ **percepts**: location and contents, e.g., $[A, Dirty]$

▷ **actions**: *Left*, *Right*, *Suck*, *NoOp*

Percept sequence	Action
$[A, Clean]$	<i>Right</i>
$[A, Dirty]$	<i>Suck</i>
$[B, Clean]$	<i>Left</i>
$[B, Dirty]$	<i>Suck</i>
$[A, Clean], [A, Clean]$	<i>Right</i>
$[A, Clean], [A, Dirty]$	<i>Suck</i>
$[A, Clean], [B, Clean]$	<i>Left</i>
$[A, Clean], [B, Dirty]$	<i>Suck</i>
$[A, Dirty], [A, Clean]$	<i>Right</i>
$[A, Dirty], [A, Dirty]$	<i>Suck</i>
⋮	⋮
$[A, Clean], [A, Clean], [A, Clean]$	<i>Right</i>
$[A, Clean], [A, Clean], [A, Dirty]$	<i>Suck</i>
⋮	⋮

▷ **Science Question**: What is the *right* agent function?

▷ **AI Question**: Is there an agent architecture and an agent program that implements it.

Example: Vacuum-Cleaner World and Agent

▷ **Example 5.2.7 (Agent Program).**

procedure Reflex-Vacuum-Agent $[location, status]$ **returns** an action

if $status = Dirty$ **then return** Suck

else if $location = A$ **then return** Right

```
else if location = B then return Left
```

Table-Driven Agents

▷ **Idea:** We can just implement the agent function as a table and look up actions.

▷ We can directly implement this:

```
function Table-Driven-Agent(percept) returns an action
  persistent table /* a table of actions indexed by percept sequences */
  var percepts /* a sequence, initially empty */
  append percept to the end of percepts
  action := lookup(percepts, table)
  return action
```

▷ **Problem:** Why is this not a good idea?

- ▷ The table is much too large: even with n binary percepts whose order of occurrence does not matter, we have 2^n rows in the table.
- ▷ Who is supposed to write this table anyways, even if it “only” has a million entries?

5.3 Good Behavior \rightsquigarrow Rationality

A Video Nugget covering this section can be found at <https://fau.tv/clip/id/21844>.

Rationality

▷ **Idea:** Try to design agents that are successful! (aka. “do the right thing”)

▷ **Definition 5.3.1.** A performance measure is a function that evaluates a sequence of environments.

▷ **Example 5.3.2.** A performance measure for the vacuum cleaner world could

- ▷ award one point per square cleaned up in time T ?
- ▷ award one point per clean square per time step, minus one per move?
- ▷ penalize for $> k$ dirty squares?

▷ **Definition 5.3.3.** An agent is called rational, if it chooses whichever action maximizes the expected value of the performance measure given the percept sequence to date.

▷ **Question:** Why is rationality a good quality to aim for?

Consequences of Rationality: Exploration, Learning, Autonomy

- ▷ **Note:** a rational agent need not be perfect
 - ▷ only needs to maximize expected value (rational \neq omniscient)
 - ▷ need not predict e.g. very unlikely but catastrophic events in the future
 - ▷ percepts may not supply all relevant information (rational \neq clairvoyant)
 - ▷ if we cannot perceive things we do not need to react to them.
 - ▷ but we may need to try to find out about hidden dangers (exploration)
 - ▷ action outcomes may not be as expected (rational \neq successful)
 - ▷ but we may need to take action to ensure that they do (more often) (learning)
- ▷ **Note:** rational \leadsto exploration, learning, autonomy
- ▷ **Definition 5.3.4.** An agent is called **autonomous**, if it does not rely on the prior knowledge about the environment of the designer.
- ▷ **Autonomy** avoids fixed behaviors that can become unsuccessful in a changing environment. (anything else would be irrational)
- ▷ The agent has to learn all relevant traits, invariants, properties of the environment and actions.

PEAS: Describing the Task Environment

- ▷ **Observation:** To design a rational agent, we must specify the task environment in terms of performance measure, environment, actuators, and sensors, together called the PEAS components.
- ▷ **Example 5.3.5.** When designing an automated taxi:
 - ▷ **Performance measure:** safety, destination, profits, legality, comfort, ...
 - ▷ **Environment:** US streets/freeways, traffic, pedestrians, weather, ...
 - ▷ **Actuators:** steering, accelerator, brake, horn, speaker/display, ...
 - ▷ **Sensors:** video, accelerometers, gauges, engine sensors, keyboard, GPS, ...
- ▷ **Example 5.3.6 (Internet Shopping Agent).**
 The task environment:
 - ▷ **Performance measure:** price, quality, appropriateness, efficiency
 - ▷ **Environment:** current and future WWW sites, vendors, shippers
 - ▷ **Actuators:** display to user, follow URL, fill in form
 - ▷ **Sensors:** HTML pages (text, graphics, scripts)

Examples of Agents: PEAS descriptions

Agent Type	Performance measure	Environment	Actuators	Sensors
Chess/Go player	win/lose/draw	game board	moves	board position
Medical diagnosis system	accuracy of diagnosis	patient, staff	display questions, diagnoses	keyboard entry of symptoms
Part-picking robot	percentage of parts in correct bins	conveyor belt with parts, bins	jointed arm and hand	camera, joint angle sensors
Refinery controller	purity, yield, safety	refinery, operators	valves, pumps, heaters, displays	temperature, pressure, chemical sensors
Interactive English tutor	student's score on test	set of students, testing accuracy	display exercises, suggestions, corrections	keyboard entry

Agents

- ▷ Which are **agents**?
 - (A) James Bond.
 - (B) Your dog.
 - (C) Vacuum cleaner.
 - (D) Thermometer.
- ▷ **Answer:** reserved for the plenary sessions ~> be there!

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 96 2024-02-08

5.4 Classifying Environments

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/21869>.

It is important to understand that the type of the **environment** has a very profound effect on the **agent** design. Depending on the type, different types of agents are needed to be successful. So before we discuss common types of **agents** in section 5.5, we will classify types of **environments**.

Environment types

- ▷ **Observation 5.4.1.** *Agent design is largely determined by the type of environment it is intended for.*
- ▷ **Problem:** There is a vast number of possible kinds of **environments** in AI.
- ▷ **Solution:** Classify along a few “dimensions”. (independent characteristics)
- ▷ **Definition 5.4.2.** For an **agent** a we classify the **environment** e of a by its **type**, which is one of the following. We call e

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 97 2024-02-08

1. **fully observable**, iff the a 's sensors give it access to the complete **state** of the **environment** at any point in time, else **partially observable**.
2. **deterministic**, iff the next **state** of the **environment** is completely determined by the current **state** and a 's **action**, else **stochastic**.
3. **episodic**, iff a 's experience is divided into atomic **episodes**, where it perceives and then performs a single **action**. Crucially, the next **episode** does not depend on previous ones. **Non-episodic environments** are called **sequential**.
4. **dynamic**, iff the **environment** can change without an **action** performed by a , else **static**. If the **environment** does not change but a 's performance measure does, we call e **semidynamic**.
5. **discrete**, iff the sets of e 's state and a 's **actions** are **countable**, else **continuous**.
6. **single agent**, iff only a acts on e ; else **multi agent** (when must we count parts of e as agents?)

Some examples will help us understand the classification of **environments** better.

Environment Types (Examples)

▷ **Example 5.4.3.** Some **environments** classified:

	Solitaire	Backgammon	Internet shopping	Taxi
fully observable	No	Yes	No	No
deterministic	Yes	No	Partly	No
episodic	No	Yes	No	No
static	Yes	Semi	Semi	No
discrete	Yes	Yes	Yes	No
single agent	Yes	No	Yes (except auctions)	No

▷ **Observation 5.4.4.** *The real world is (of course) a **partially observable**, **stochastic**, **sequential**, **dynamic**, **continuous**, and **multi agent** environment. (worst case for AI)*

In the AI-1 course we will work our way from the simpler environment types to the more general ones. Each environment type will need its own agent types specialized to surviving and doing well in them.

5.5 Types of Agents

We will now discuss the main types of **agents** we will encounter in this course, get an impression of the variety, and what they can and cannot do. We will start from **simple reflex agents**, add state, and utility, and finally add learning. **A Video Nugget** covering this section can be found at <https://fau.tv/clip/id/21926>.

Agent types

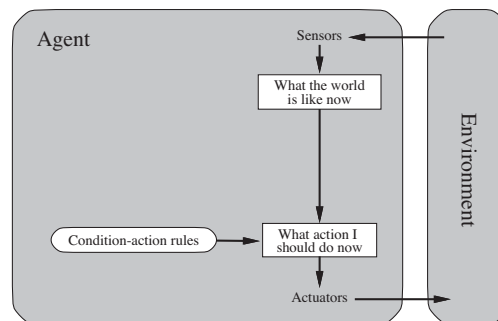

▷ **Observation:** So far we have described (and analyzed) **agents** only by their be-

havior (cf. agent function $f: \mathcal{P}^* \rightarrow \mathcal{A}$).

- ▷ **Problem:** This does not help us to build agents. (the goal of AI)
 - ▷ To build an agent, we need to fix an agent architecture and come up with an agent program that runs on it.
 - ▷ **Preview:** Four basic types of agent architectures in order of increasing generality:
 1. simple reflex agents
 2. model-based agents
 3. goal-based agents
 4. utility-based agents
- All these can be turned into learning agents.

Simple reflex agents

- ▷ **Definition 5.5.1.** A simple reflex agent is an agent a that only bases its actions on the last percept: so the agent function simplifies to $f_a: \mathcal{P} \rightarrow \mathcal{A}$.
- ▷ **Agent Schema:**

- ▷ **Example 5.5.2 (Agent Program).**

```
procedure Reflex-Vacuum-Agent [location,status] returns an action
  if status = Dirty then ...
```

Simple reflex agents (continued)

- ▷ **General Agent Program:**
- ```
function Simple-Reflex-Agent (percept) returns an action
 persistent: rules /* a set of condition-action rules*/
 state := Interpret-Input(percept)
 rule := Rule-Match(state,rules)
```

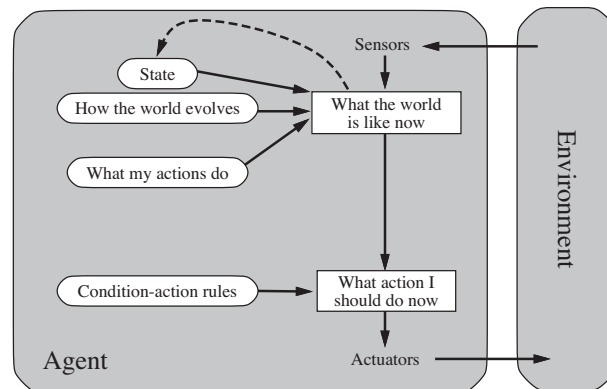

```
action := Rule-action[rule]
```

```
return action
```

- ▷ **Problem:** Simple reflex agents can only react to the perceived state of the environment, not to changes.
- ▷ **Example 5.5.3.** Automobile tail lights signal braking by brightening. A simple reflex agent would have to compare subsequent percepts to realize.
- ▷ **Problem:** Partially observable environments get simple reflex agents into trouble.
- ▷ **Example 5.5.4.** Vacuum cleaner robot with defective location sensor  $\leadsto$  infinite loops.

## Model-based Reflex Agents: Idea

- ▷ **Idea:** Keep track of the state of the world we cannot see in an internal model.
- ▷ **Agent Schema:**

## Model-based Reflex Agents: Definition

- ▷ **Definition 5.5.5.** A model-based agent is an agent whose actions depend on
  - ▷ a world model: a set  $S$  of possible states.
  - ▷ a sensor model  $S$  that given a state  $s$  and a percepts  $p$  determines a new state  $S(s, p)$ .
  - ▷ a transition model  $T$ , that predicts a new state  $T(s, a)$  from a state  $s$  and an action  $a$ .
  - ▷ An action function  $f$  that maps (new) states to an actions.

If the world model of a model-based agent  $A$  is in state  $s$  and  $A$  has taken action  $a$ ,  $A$  will transition to state  $s' = T(S(p, s), a)$  and take action  $a' = f(s')$ .

- ▷ **Note:** As different **percept** sequences lead to different **states**, so the **agent function**  $f_a: \mathcal{P}^* \rightarrow \mathcal{A}$  no longer depends only on the last **percept**.
- ▷ **Example 5.5.6 (Tail Lights Again).** **Model-based agents** can do the 101 if the **states** include a concept of tail light brightness.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 103 2024-02-08

### Model-Based Agents (continued)

- ▷ **Observation 5.5.7.** The **agent program** for a **model-based agent** is of the following form:

```

function Model-Based-Agent (percept) returns an action
 var state /* a description of the current state of the world */
 persistent rules /* a set of condition-action rules */
 var action /* the most recent action, initially none */

 state := Update-State(state,action,percept)
 rule := Rule-Match(state,rules)
 action := Rule-action(rule)
 return action

```

- ▷ **Problem:** Having a **world model** does not always determine what to do (**rationally**).
- ▷ **Example 5.5.8.** Coming to an intersection, where the **agent** has to decide between going left and right.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 104 2024-02-08

### Goal-based Agents

- ▷ **Problem:** A **world model** does not always determine what to do (**rationally**).
- ▷ **Observation:** Having a goal in mind does! (determines future actions)
- ▷ **Agent Schema:**

The diagram illustrates the Agent Schema. On the left, the **Agent** contains several components: **State**, **How the world evolves**, **What my actions do**, and **Goals**. These components feed into two central boxes: **What the world is like now** and **What it will be like if I do action A**. **Sensors** from the **Environment** provide input to the first box. The second box leads to **What action I should do now**, which is then executed by **Actuators** back into the **Environment**. A dashed arrow indicates a feedback loop from the final action back to the **State**.

## Goal-based agents (continued)

▷ **Definition 5.5.9.** A **goal-based agent** is a **model-based agent** with **transition model**  $T$  that deliberates **actions** based on **goals** and a **world model**: It employs

- ▷ a set  $\mathcal{G}$  of **goals** and a **goal function**  $f$  that given a (new) **state**  $s'$  selects an **action**  $a$  to best reach  $\mathcal{G}$ .

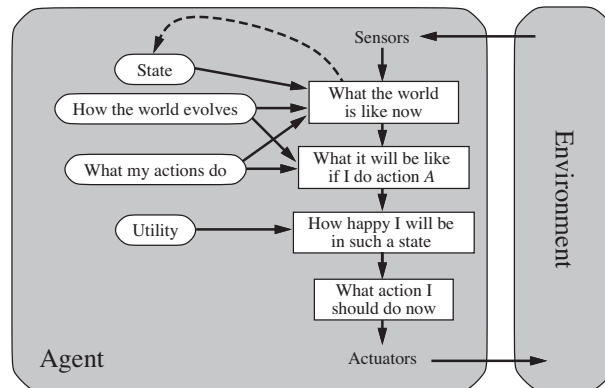

The **action function** is then  $s \mapsto f(T(s), \mathcal{G})$ .

- ▷ **Observation:** A **goal-based agent** is more flexible in the knowledge it can utilize.
- ▷ **Example 5.5.10.** A **goal-based agent** can easily be changed to go to a new destination, a **model-based agent's** rules make it go to exactly one destination.

## Utility-based Agents

▷ **Definition 5.5.11.** A **utility-based agent** uses a **world model** along with a **utility function** that models its preferences among the **states** of that world. It chooses the **action** that leads to the best **expected utility**.

▷ **Agent Schema:**

## Utility-based vs. Goal-based Agents

- ▷ **Question:** What is the difference between **goal-based** and **utility-based agents**?
- ▷ **Utility-based Agents are a Generalization:** We can always force **goal-directedness** by a **utility function** that only rewards **goal states**.
- ▷ **Goal-based Agents can do less:** A **utility function** allows **rational** decisions where

mere **goals** are inadequate:

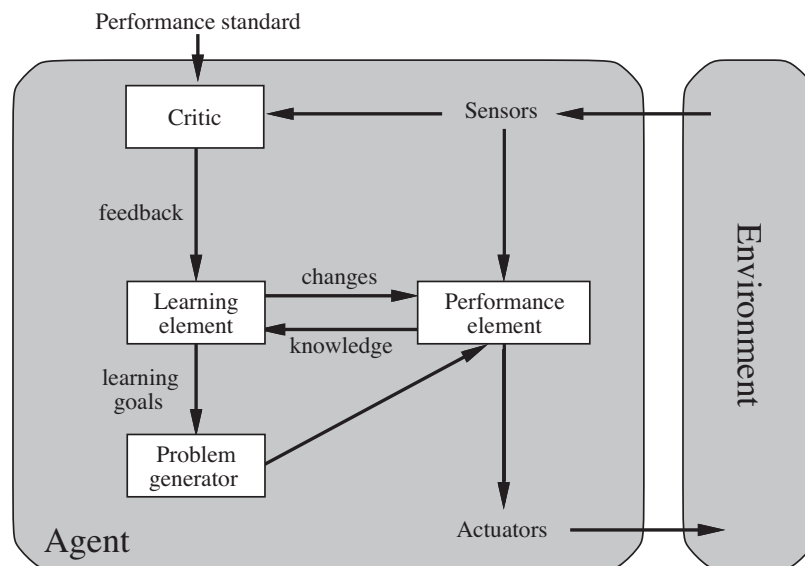

- ▷ conflicting **goals** (utility gives tradeoff to make rational decisions)
- ▷ **goals** obtainable by **uncertain actions** (utility × likelihood helps)

## Learning Agents

- ▷ **Definition 5.5.12.** A **learning agent** is an **agent** that augments the **performance element** – which determines **actions** from **percept** sequences with
  - ▷ a **learning element** which makes improvements to the **agent's** components,
  - ▷ a **critic** which gives feedback to the **learning element** based on an external **performance standard**,
  - ▷ a **problem generator** which suggests **actions** that lead to new and informative experiences.
- ▷ The **performance element** is what we took for the whole **agent** above.

## Learning Agents

- ▷ **Agent Schema:**

## Learning Agents: Example

- ▷ **Example 5.5.13 (Learning Taxi Agent).** It has the components
  - ▷ **Performance element:** the knowledge and procedures for selecting driving actions. (this controls the actual driving)
  - ▷ **critic:** observes the world and informs the learning element (e.g. when passengers complain brutal braking)
  - ▷ **Learning element** modifies the braking rules in the performance element (e.g. earlier, softer)
  - ▷ **Problem generator** might experiment with braking on different road surfaces
- ▷ The **learning element** can make changes to any “knowledge components” of the diagram, e.g. in the
  - ▷ model from the **percept** sequence (how the world evolves)
  - ▷ success likelihoods by observing **action** outcomes (what my actions do)
- ▷ **Observation:** here, the passenger complaints serve as part of the “external performance standard” since they correlate to the overall outcome – e.g. in form of tips or blacklists.

## Domain-Specific vs. General Agents

| Domain-Specific Agent                                                                                                                                    | vs. | General Agent                                                                                                     |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|-----|-------------------------------------------------------------------------------------------------------------------|
|  <p>Duell Kasparow gegen Deep Blue (1997): Demütigende Niederlage</p> | vs. |                               |
| Solver specific to a particular problem (“domain”).                                                                                                      | vs. | Solver based on <i>description</i> in a general problem-description language (e.g., the rules of any board game). |
| More <b>efficient</b> .                                                                                                                                  | vs. | Much less design/maintenance work.                                                                                |

- ▷ What kind of **agent** are you?

## 5.6 Representing the Environment in Agents

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/21925>.

We now come to a very important topic, which has a great influence on agent design: how does the agent represent the environment. After all, in all agent designs above (except the **simple**

reflex agent) maintain a notion of world state and how the world state evolves given percepts and actions. The form of this model determines the algorithms.

## Representing the Environment in Agents

- ▷ We have seen various components of agents that answer questions like
  - ▷ *What is the world like now?*
  - ▷ *What action should I do now?*
  - ▷ *What do my actions do?*
- ▷ **Next natural question:** How do these work? (see the rest of the course)
- ▷ **Important Distinction:** How the agent implements the world model.
- ▷ **Definition 5.6.1.** We call a state representation
  - ▷ **atomic**, iff it has no internal structure (black box)
  - ▷ **factored**, iff each state is characterized by attributes and their values.
  - ▷ **structured**, iff the state includes representations of objects and their relationships.

## Atomic/Factored/Structured State Representations

- ▷ **Schematically:** we can visualize the three kinds by

- ▷ **Example 5.6.2.** Consider the problem of finding a driving route from one end of a country to the other via some sequence of cities.
  - ▷ In an **atomic** representation the state is represented by the name of a city.
  - ▷ In a **factored** representation we may have attributes “gps-location”, “gas”, ... (allows information sharing between states and uncertainty)
  - ▷ But how to represent a situation, where a large truck blocking the road, since it is trying to back into a driveway, but a loose cow is blocking its path. (attribute “TruckAheadBackingIntoDairyFarmDrivewayBlockedByLooseCow” is unlikely)
  - ▷ In a **structured** representation, we can have objects for trucks, cows, etc. and their relationships.

## Summary

---

- ▷ Agents interact with environments through actuators and sensors.
- ▷ The agent function describes what the agent does in all circumstances.
- ▷ The performance measure evaluates the environment sequence.
- ▷ A perfectly rational agent maximizes expected performance.
- ▷ Agent programs implement (some) agent functions.
- ▷ PEAS descriptions define task environments.
- ▷ Environments are categorized along several dimensions:  
fully observable? deterministic? episodic? static? discrete? single agent?
- ▷ Several basic agent architectures exist:  
reflex, model-based, goal-based, utility-based

## Part II

# General Problem Solving

This part introduces search-based methods for general problem solving using [atomic](#) and [factored](#) representations of states.

Concretely, we discuss the basic techniques of search-based [symbolic AI](#). First in the shape of classical and [heuristic search](#) and [adversarial search](#) paradigms. Then in constraint propagation, where we see the first instances of inference-based methods.

# Chapter 6

## Problem Solving and Search

In this chapter, we will look at a class of [algorithms](#) called [search algorithms](#). These are [algorithms](#) that help in quite general situations, where there is a precisely described problem, that needs to be solved. Hence the name “General Problem Solving” for the area.

### 6.1 Problem Solving

[A Video Nugget](#) covering this section can be found at <https://fau.tv/clip/id/21927>.

Before we come to the search [algorithms](#) themselves, we need to get a grip on the types of problems themselves and how we can represent them, and on what the various types entail for the problem solving process.

The first step is to classify the problem solving process by the amount of knowledge we have available. It makes a difference, whether we know all the factors involved in the problem before we actually are in the situation. In this case, we can solve the problem in the abstract, i.e. make a plan before we actually enter the situation (i.e. [offline](#)), and then when the problem arises, only execute the plan. If we do not have complete knowledge, then we can only make partial plans, and have to be in the situation to obtain new knowledge (e.g. by observing the effects of our actions or the actions of others). As this is much more difficult we will restrict ourselves to [offline problem solving](#).

#### Problem Solving: Introduction

- ▷ **Recap:** Agents perceive the [environment](#) and compute an [action](#).
- ▷ **In other words:** Agents continually solve “the problem of what to do next”.
- ▷ **AI Goal:** Find [algorithms](#) that help solving problems in general.
- ▷ **Idea:** If we can describe/represent problems in a standardized way, we may have a chance to find general [algorithms](#).
- ▷ **Concretely:** We will use the following two concepts to describe problems
  - ▷ **States:** A set of possible situations in our problem domain ( $\hat{=}$  [environments](#))
  - ▷ **Actions:** that get us from one [state](#) to another. ( $\hat{=}$  [agents](#))

A sequence of [actions](#) is a [solution](#), if it brings us from an [initial state](#) to a [goal state](#). [Problem solving](#) computes [solutions](#) from [problem formulations](#).

- ▷ **Definition 6.1.1.** In **offline problem solving** an **agent** computing an action sequence based complete knowledge of the **environment**.
- ▷ **Remark 6.1.2.** Offline problem solving only works in **fully observable**, **deterministic**, **static**, and **episodic environments**.
- ▷ **Definition 6.1.3.** In **online problem solving** an **agent** computes one **action** at a time based on incoming **perceptions**.
- ▷ **This Semester:** We largely restrict ourselves to **offline problem solving**. (**easier**)

We will use the following problem as a running example. It is simple enough to fit on one slide and complex enough to show the relevant features of the problem solving **algorithms** we want to talk about.

## Example: Traveling in Romania

- ▷ **Scenario:** An **agent** is on holiday in Romania; currently in Arad; flight home leaves tomorrow from Bucharest; how to get there? We have a map:

- ▷ **Formulate the Problem:**
  - ▷ **States:** various cities.
  - ▷ **Actions:** drive between cities.
- ▷ **Solution:** Appropriate sequence of cities, e.g.: Arad, Sibiu, Fagaras, Bucharest

Given this example to fortify our intuitions, we can now turn to the formal definition of problem formulation and their solutions.

## Problem Formulation

- ▷ **Definition 6.1.4.** A **problem formulation** models a situation using **states** and **actions** at an appropriate level of abstraction. (do not model things like “put on my left sock”, etc.)
  - ▷ it describes the **initial state** (we are in Arad)

- ▷ it also limits the objectives by specifying **goal states**. (excludes, e.g. to stay another couple of weeks.)

A **solution** is a sequence of **actions** that leads from the **initial state** to a **goal state**.

**Problem solving** computes **solutions** from **problem formulations**.

- ▷ Finding the right level of abstraction and the required (not more!) information is often the key to success.

## The Math of Problem Formulation: Search Problems

- ▷ **Definition 6.1.5.** A **search problem**  $\langle \mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$  consists of a **set**  $\mathcal{S}$  of **states**, a **set**  $\mathcal{A}$  of **actions**, and a **transition model**  $\mathcal{T}: \mathcal{A} \times \mathcal{S} \rightarrow \mathcal{P}(\mathcal{S})$  that assigns to any **action**  $a \in \mathcal{A}$  and **state**  $s \in \mathcal{S}$  a **set of successor states**.

Certain **states** in  $\mathcal{S}$  are designated as **goal states** (also called **terminal state**) ( $\mathcal{G} \subseteq \mathcal{S}$ ) and **initial states**  $\mathcal{I} \subseteq \mathcal{S}$ .

- ▷ **Definition 6.1.6.** We say that an **action**  $a \in \mathcal{A}$  is **applicable** in **state**  $s \in \mathcal{S}$ , iff  $\mathcal{T}(a, s) \neq \emptyset$ . We call  $\mathcal{T}_a: \mathcal{S} \rightarrow \mathcal{P}(\mathcal{S})$  with  $\mathcal{T}_a(s) := \mathcal{T}(a, s)$  the **result relation** for  $a$  and  $\mathcal{T}_{\mathcal{A}} := \bigcup_{a \in \mathcal{A}} \mathcal{T}_a$  the **result relation** of  $\Pi$ .

- ▷ **Definition 6.1.7.** The **graph**  $\langle \mathcal{S}, \mathcal{T}_{\mathcal{A}} \rangle$  is called the **state space** induced by  $\Pi$ .

- ▷ **Definition 6.1.8.** A **solution** for a **search problem**  $\langle \mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$  consists of a **sequence**  $a_1, \dots, a_n$  of **actions** such that for all  $1 \leq i < n$

- ▷  $a_i$  is **applicable** to **state**  $s_{(i-1)}$ , where  $s_0 \in \mathcal{I}$ ,
- ▷  $s_i \in \mathcal{T}_{a_i}(s_{(i-1)})$ , and  $s_n \in \mathcal{G}$ .

- ▷ **Idea:** A **solution** bring us from  $\mathcal{I}$  to a **goal state**.

- ▷ **Definition 6.1.9.** Often we add a **cost function**  $c: \mathcal{A} \rightarrow \mathbb{R}_0^+$  that associates a **step cost**  $c(a)$  to an **action**  $a \in \mathcal{A}$ . The **cost** of a **solution** is the sum of the **step costs** of its **actions**.

**Observation:** The formulation of problems from Definition 6.1.5 uses an **atomic** (black-box) **state** representation. It has enough functionality to construct the **state space** but nothing else. We will come back to this in slide 122.

*Remark 6.1.10.* Note that **search problems** formalize **problem formulations** by making many of the implicit constraints explicit.

## Structure Overview: Search Problem

- ▷ The structure overview for **search problems**:

|                                                                                   |   |                                                                                                                                                                                                                                                                             |                                                                                      |
|-----------------------------------------------------------------------------------|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| search problem                                                                    | = | $\left\langle \begin{array}{ll} \mathcal{S} & \text{Set} \\ \mathcal{A} & \text{Set} \\ \mathcal{T} & \mathcal{A} \times \mathcal{S} \rightarrow \mathcal{P}(\mathcal{S}) \\ \mathcal{I} & \mathcal{S} \\ \mathcal{G} & \mathcal{P}(\mathcal{S}) \end{array} \right\rangle$ | <p>states,<br/>actions,<br/>transition model,<br/>initial state,<br/>goal states</p> |
|  |   | Michael Kohlhase: Artificial Intelligence 1                                                                                                                                                                                                                                 | 120                                                                                  |
|                                                                                   |   | 2024-02-08                                                                                                                                                                                                                                                                  |   |

We will now specialize Definition 6.1.5 to **deterministic, fully observable environments**, i.e. environments where actions only have one – assured – outcome state.

### Search Problems in deterministic, fully observable Environments

- ▷ This semester, we will restrict ourselves to **search problems**, where (extend in AI II)
  - ▷  $|\mathcal{T}(a, s)| \leq 1$  for the **transition models** and  $\Leftrightarrow$  **deterministic environment**
  - ▷  $\mathcal{I} = \{s_0\}$   $\Leftrightarrow$  **fully observable environment**
- Definition 6.1.11.** We call a **search problem** with **transition model**  $\mathcal{T}$  **deterministic**, iff  $|\mathcal{T}(a, s)| \leq 1$ .
- ▷
- ▷ **Definition 6.1.12.** In a **deterministic search problem**,  $\mathcal{T}_a$  induces **partial function**  $S_a: \mathcal{S} \rightarrow \mathcal{S}$  whose **natural domain** is the **set of states** where  $a$  is **applicable**:  $S_a(s) := s'$  if  $\mathcal{T}_a = \{s'\}$  and **undefined at**  $s$  otherwise. We call  $S_a$  the **successor function** for  $a$  and  $S_a(s)$  the **successor state** of  $s$ .
- ▷ **Definition 6.1.13.** The predicate that tests for **goal states** is called a **goal test**.

|                                                                                     |  |                                             |                                                                                       |
|-------------------------------------------------------------------------------------|--|---------------------------------------------|---------------------------------------------------------------------------------------|
|  |  | Michael Kohlhase: Artificial Intelligence 1 | 121                                                                                   |
|                                                                                     |  | 2024-02-08                                  |  |

### Blackbox/Declarative Problem Descriptions

- ▷ **Observation:**  $\langle \mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$  from Definition 6.1.5 is essentially a **blackbox description**; it (think programming API)
  - ▷ provides the functionality needed to construct a **state space**, but
  - ▷ gives the **algorithm** no information about the **problem**.
- ▷ **Definition 6.1.14.** A **declarative description** (also called **whitebox description**) describes the problem itself  $\leadsto$  **problem description language**
- ▷ **Example 6.1.15 (Planning Problems as Declarative Descriptions).**

The STRIPS language describes **planning problems** in terms of

  - ▷ a set  $P$  of **propositional variables** (propositions)
  - ▷ a set  $I \subseteq P$  of **propositions** true in the **initial state**.
  - ▷ a set  $G \subseteq P$ , where **state**  $s \subseteq P$  is a **goal state** if  $G \subseteq s$

- ▷ a set  $A$  of actions, each  $a \in A$  with preconditions  $\text{pre}_a$ , add list  $\text{add}_a$ , and delete list  $\text{del}_a$ :  $a$  is applicable, if  $\text{pre}_a \subseteq s$ , the result state is then  $(s \cup \text{add}_a) \setminus \text{del}_a$ ,
  - ▷ a function  $c$  that maps all actions  $a$  to their cost  $c(a)$ .
- ▷ **Observation 6.1.16.** *Declarative descriptions are strictly more powerful than black-box descriptions: they induce blackbox descriptions, but also allow to analyze/simplify the problem.*
- ▷ We will come back to this later  $\rightsquigarrow$  planning.

## 6.2 Problem Types

Note that the definition of a search problem is very general, it applies to many many real-world problems. So we will try to characterize these by difficulty. **A Video Nugget** covering this section can be found at <https://fau.tv/clip/id/21928>.

### Problem types

- ▷ **Definition 6.2.1.** A search problem is called a **single state problem**, iff it is
  - ▷ fully observable (at least the initial state)
  - ▷ deterministic (unique successor states)
  - ▷ static (states do not change other than by our own actions)
  - ▷ discrete (a countable number of states)
- ▷ **Definition 6.2.2.** A search problem is called a **multi state problem**
  - ▷ states partially observable (e.g. multiple initial states)
  - ▷ deterministic, static, discrete
- ▷ **Definition 6.2.3.** A search problem is called a **contingency problem**, iff
  - ▷ the environment is non deterministic (solution can branch, depending on contingencies)
  - ▷ the state space is unknown (like a baby, agent has to learn about states and actions)

We will explain these problem types with another example. The problem  $\mathcal{P}$  is very simple: We have a vacuum cleaner and two rooms. The vacuum cleaner is in one room at a time. The floor can be dirty or clean.

The possible states are determined by the position of the vacuum cleaner and the information, whether each room is dirty or not. Obviously, there are eight states:  $S = \{1, 2, 3, 4, 5, 6, 7, 8\}$  for simplicity.

The goal is to have both rooms clean, the vacuum cleaner can be anywhere. So the set  $\mathcal{G}$  of goal states is  $\{7, 8\}$ . In the single-state version of the problem,  $[right, suck]$  shortest solution, but  $[suck, right, suck]$  is also one. In the multiple-state version we have

$$[right\{2, 4, 6, 8\}, suck\{4, 8\}, left\{3, 7\}, suck\{7\}]$$

### Example: vacuum-cleaner world

#### ▷ Single-state Problem:

▷ Start in 5

▷ **Solution:**  $[right, suck]$

#### ▷ Multiple-state Problem:

▷ Start in  $\{1, 2, 3, 4, 5, 6, 7, 8\}$

▷ **Solution:**  $[right, suck, left, suck]$

|              |                              |
|--------------|------------------------------|
| <i>right</i> | $\rightarrow \{2, 4, 6, 8\}$ |
| <i>suck</i>  | $\rightarrow \{4, 8\}$       |
| <i>left</i>  | $\rightarrow \{3, 7\}$       |
| <i>suck</i>  | $\rightarrow \{7\}$          |

### Example: Vacuum-Cleaner World (continued)

#### ▷ Contingency Problem:

▷ Murphy's Law: *suck* can dirty a clean carpet

▷ Local sensing: *dirty/notdirty* at location only

▷ Start in:  $\{1, 3\}$

▷ **Solution:**  $[suck, right, suck]$

|              |                        |
|--------------|------------------------|
| <i>suck</i>  | $\rightarrow \{5, 7\}$ |
| <i>right</i> | $\rightarrow \{6, 8\}$ |
| <i>suck</i>  | $\rightarrow \{6, 8\}$ |

▷ **better:**  $[suck, right, \text{if dirt then suck}]$  (decide whether in 6 or 8 using local sensing)

In the contingency version of  $\mathcal{P}$  a solution is the following:

$[suck\{5, 7\}, right \rightarrow \{6, 8\}, suck \rightarrow \{6, 8\}, suck\{5, 7\}]$

etc. Of course, local sensing can help: narrow  $\{6, 8\}$  to  $\{6\}$  or  $\{8\}$ , if we are in the first, then suck.

### Single-state problem formulation

▷ Defined by the following four items

1. Initial state: (e.g. *Arad*)
2. Successor function  $S_a(s)$ : (e.g.  $S_{goZer} = \{(Arad, Zerind), (goSib, Sibiu), \dots\}$ )
3. Goal test: (e.g.  $x = Bucharest$  (explicit test) )  
 $noDirt(x)$  (implicit test)
4. Path cost (optional): (e.g. sum of distances, number of operators executed, etc.)

▷ Solution: A sequence of actions leading from the initial state to a goal state.

Michael Kohlhase: Artificial Intelligence 1
126
2024-02-08

“Path cost”: There may be more than one solution and we might want to have the “best” one in a certain sense.

### Selecting a state space

- ▷ **Abstraction:** Real world is absurdly complex!  
State space must be abstracted for problem solving.
- ▷ **(Abstract) state:** Set of real states.
- ▷ **(Abstract) operator:** Complex combination of real actions.
- ▷ **Example:** *Arad* → *Zerind* represents complex set of possible routes.
- ▷ **(Abstract) solution:** Set of real paths that are solutions in the real world.

Michael Kohlhase: Artificial Intelligence 1
127
2024-02-08

“State”: e.g., we don’t care about tourist attractions found in the cities along the way. But this is problem dependent. In a different problem it may well be appropriate to include such information in the notion of state.

“Realizability”: one could also say that the abstraction must be sound wrt. reality.

### Example: The 8-puzzle

|   |   |   |
|---|---|---|
| 7 | 2 | 4 |
| 5 |   | 6 |
| 8 | 3 | 1 |

|   |   |   |
|---|---|---|
|   | 1 | 2 |
| 3 | 4 | 5 |
| 6 | 7 | 8 |

Start State
Goal State

|           |                              |
|-----------|------------------------------|
| States    | integer locations of tiles   |
| Actions   | <i>left, right, up, down</i> |
| Goal test | = goal state?                |
| Path cost | 1 per move                   |

Michael Kohlhase: Artificial Intelligence 1
128
2024-02-08

How many states are there?  $N$  factorial, so it is not obvious that the problem is in NP. One needs to show, for example, that polynomial length solutions do always exist. Can be done by

combinatorial arguments on [state space graph](#) (really ?).

Some rule-books give a different goal state for the 8-puzzle: starting with 1, 2, 3 in the top row and having the hold in the lower right corner. This is completely irrelevant for the example and its significance to AI-1.

### Example: Vacuum-cleaner

|           |                                      |
|-----------|--------------------------------------|
| States    | integer dirt and robot locations     |
| Actions   | <i>left, right, suck, noOp</i>       |
| Goal test | <i>notdirty?</i>                     |
| Path cost | 1 per operation (0 for <i>noOp</i> ) |

### Example: Robotic assembly

|           |                                                                                       |
|-----------|---------------------------------------------------------------------------------------|
| States    | real-valued coordinates of robot joint angles and parts of the object to be assembled |
| Actions   | continuous motions of robot joints                                                    |
| Goal test | assembly complete?                                                                    |
| Path cost | time to execute                                                                       |

### General Problems

- ▷ **Question:** Which are “Problems”?

- (A) You didn't understand any of the lecture.
  - (B) Your bus today will probably be late.
  - (C) Your vacuum cleaner wants to clean your apartment.
  - (D) You want to win a chess game.
- ▷ **Answer:** reserved for the plenary sessions ~ be there!

## 6.3 Search

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/21956>.

### Tree Search Algorithms

- ▷ **Note:** The **state space** of a **search problem**  $\langle \mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$  is a **graph**  $\langle \mathcal{S}, \mathcal{T}_{\mathcal{A}} \rangle$ .
- ▷ As **graphs** are difficult to compute with, we often compute a corresponding **tree** and work on that. (standard trick in graph algorithms)
- ▷ **Definition 6.3.1.** Given a **search problem**  $\mathcal{P} := \langle \mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$ , the **tree search algorithm** consists of the simulated exploration of **state space**  $\langle \mathcal{S}, \mathcal{T}_{\mathcal{A}} \rangle$  in a **search tree** formed by successively **expanding** already explored **states**. (offline algorithm)

```

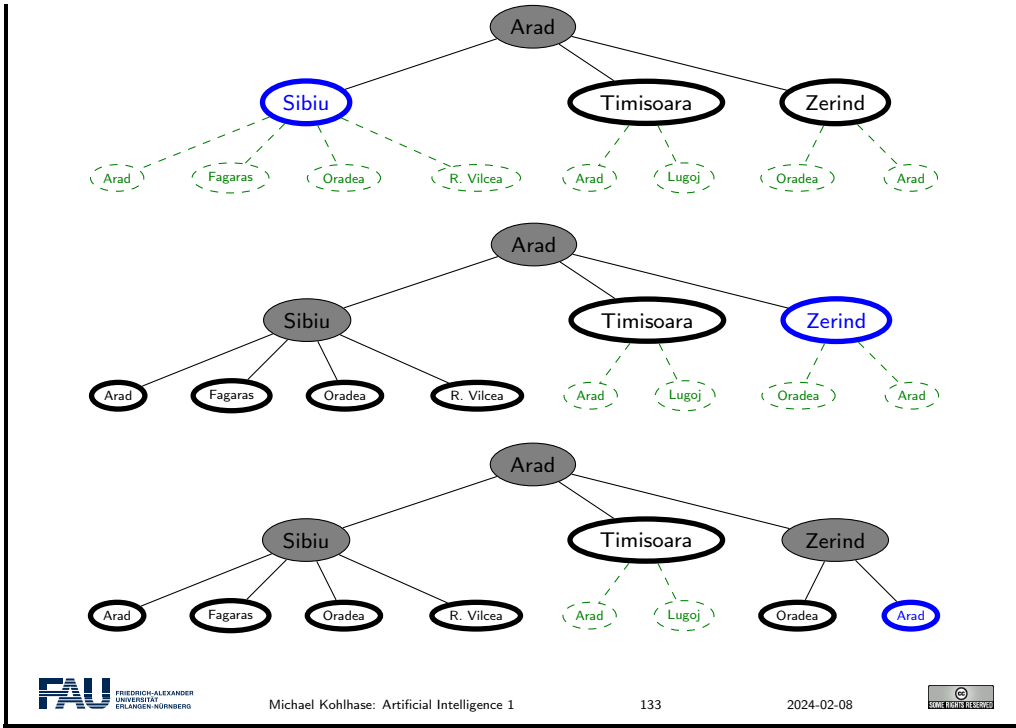

procedure Tree-Search (problem, strategy) : <a solution or failure>
 <initialize the search tree using the initial state of problem>
 loop
 if <there are no candidates for expansion> <return failure> end if
 <choose a leaf node for expansion according to strategy>
 if <the node contains a goal state> return <the corresponding solution>
 else <expand the node and add the resulting nodes to the search tree>
 end if
 end loop
end procedure

```

We **expand** a **node**  $n$  by generating all **successors** of  $n$  and inserting them as **children** of  $n$  in the **search tree**.

### Tree Search: Example

### Implementation: States vs. nodes

- ▷ **Recap:** A *state* is a (representation of) a physical configuration.
- ▷ **Remark:** The *nodes* of a search tree are implemented as a data structure that includes *accessors* for *parent*, *children*, *depth*, *path cost*, etc.

- ▷ **Observation:** Paths in the search tree correspond to paths in the state space.
- ▷ **Observation:** As a search tree node has access to parents, we can read off the solution from a goal node.
- ▷ **Definition 6.3.2.** A *goal node* is a node labeled with a goal state
- ▷ **Definition 6.3.3.** We define the *path cost* of a node  $n$  in a search tree  $T$  to be the sum of the *step costs* on the path from  $n$  to the root of  $T$ .

## Implementation of Search Algorithms

```

procedure Tree_Search (problem, strategy)
 fringe := insert(make_node(initial_state(problem)))
 loop
 if fringe <is empty> fail end if
 node := first(fringe, strategy)
 if NodeTest(State(node)) return State(node)
 else fringe := insert_all(expand(node, problem), strategy)
 end if
 end loop
end procedure

```

▷ **Definition 6.3.4.** The **fringe** is a **list nodes** not yet **expanded** in **tree search**.

▷ It is ordered by the **strategy**. (see below)

- STATE gives the state that is represented by *node*
- EXPAND = creates new nodes by applying possible actions to *node*
- MAKE-QUEUE creates a queue with the given elements.
- FRINGE holds the queue of nodes not yet considered.
- REMOVE-FIRST returns first element of queue and as a side effect removes it from FRINGE.
- STATE gives the state that is represented by *node*.
- EXPAND applies all operators of the problem to the current node and yields a set of new nodes.
- INSERT inserts an element into the current *fringe* queue. This can change the behavior of the search.
- INSERT-ALL Perform INSERT on set of elements.

## Search strategies

▷ **Definition 6.3.5.** A **strategy** is a **function** that picks a **node** from the **fringe** of a **search tree**. (equivalently, orders the fringe and picks the first.)

▷ **Definition 6.3.6 (Important Properties of Strategies).**

|                  |                                                      |
|------------------|------------------------------------------------------|
| completeness     | does it always find a <b>solution</b> if one exists? |
| time complexity  | number of <b>nodes</b> generated/expanded            |
| space complexity | maximum number of <b>nodes</b> in memory             |
| optimality       | does it always find a least cost <b>solution</b> ?   |

▷ **Time and space complexity measured in terms of:**

|     |                                                                           |
|-----|---------------------------------------------------------------------------|
| $b$ | maximum <b>branching factor</b> of the <b>search tree</b>                 |
| $d$ | minimal <b>graph depth</b> of a <b>solution</b> in the <b>search tree</b> |
| $m$ | maximum <b>graph depth</b> of the <b>search tree</b> (may be $\infty$ )   |

Complexity means here always *worst-case complexity!*

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 136 2024-02-08

Note that there can be *infinite* branches, see the search tree for Romania.

## 6.4 Uninformed Search Strategies

**Video Nuggets** covering this section can be found at <https://fau.tv/clip/id/21994> and <https://fau.tv/clip/id/21995>.

Uninformed search strategies

- ▷ **Definition 6.4.1.** We speak of an *uninformed search algorithm*, if it only uses the information available in the problem definition.
- ▷ **Next:** Frequently used search algorithms
  - ▷ Breadth first search
  - ▷ Uniform cost search
  - ▷ Depth first search
  - ▷ Depth limited search
  - ▷ Iterative deepening search

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 137 2024-02-08

The opposite of *uninformed* search is *informed* or *heuristic* search that uses a *heuristic function* that adds external guidance to the search process. In the Romania example, one could add the *heuristic* to prefer cities that lie in the general direction of the goal (here SE).

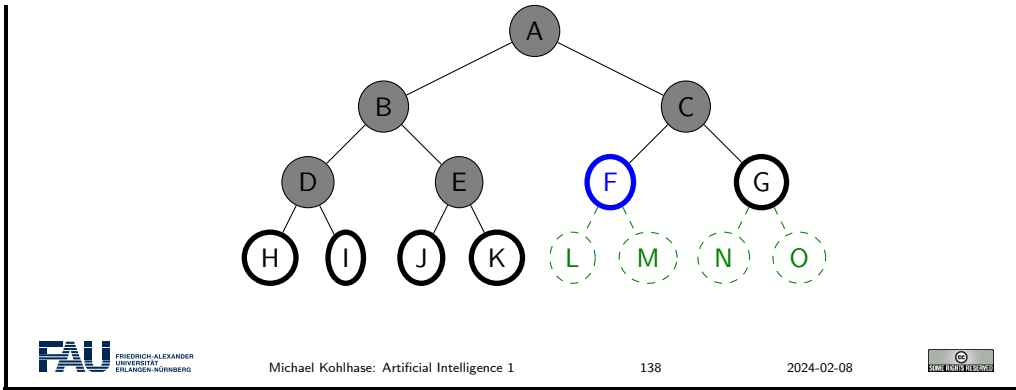

Even though *heuristic search* is usually much more *efficient*, *uninformed* search is important nonetheless, because many problems do not allow to extract good *heuristics*.

### 6.4.1 Breadth-First Search Strategies

Breadth-First Search

- ▷ **Idea:** Expand the shallowest *unexpanded node*.
- ▷ **Definition 6.4.2.** The *breadth first search (BFS) strategy* treats the *fringe* as a *FIFO queue*, i.e. *successors* go in at the end of the *fringe*.
- ▷ **Example 6.4.3 (Synthetic).**

We will now apply the **breadth first search strategy** to our running example: Traveling in Romania. Note that we leave out the green dashed nodes that allow us a preview over what the search tree will look like (if expanded). This gives a much cleaner picture we assume that the readers already have grasped the mechanism sufficiently.

### Breadth-first search: Properties

|                  |                                                                           |
|------------------|---------------------------------------------------------------------------|
| Completeness     | Yes (if $b$ is finite)                                                    |
| Time complexity  | $1+b+b^2+b^3+\dots+b^d$ , so $\mathcal{O}(b^d)$ , i.e. exponential in $d$ |
| Space complexity | $\mathcal{O}(b^d)$ (fringe may be whole level)                            |
| Optimality       | Yes (if cost = 1 per step), not optimal in general                        |

- ▷ **Disadvantage:** Space is the big problem (can easily generate nodes at 500MB/sec  $\hat{=}$  1.8TB/h)
- ▷ **Optimal?:** No! If cost varies for different steps, there might be better solutions below the level of the first one.
- ▷ An alternative is to generate *all* solutions and then pick an optimal one. This works only, if  $m$  is finite.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 140 2024-02-08

The next idea is to let cost drive the search. For this, we will need a non-trivial cost function: we will take the distance between cities, since this is very natural. Alternatives would be the driving time, train ticket cost, or the number of tourist attractions along the way.

Of course we need to update our problem formulation with the necessary information.

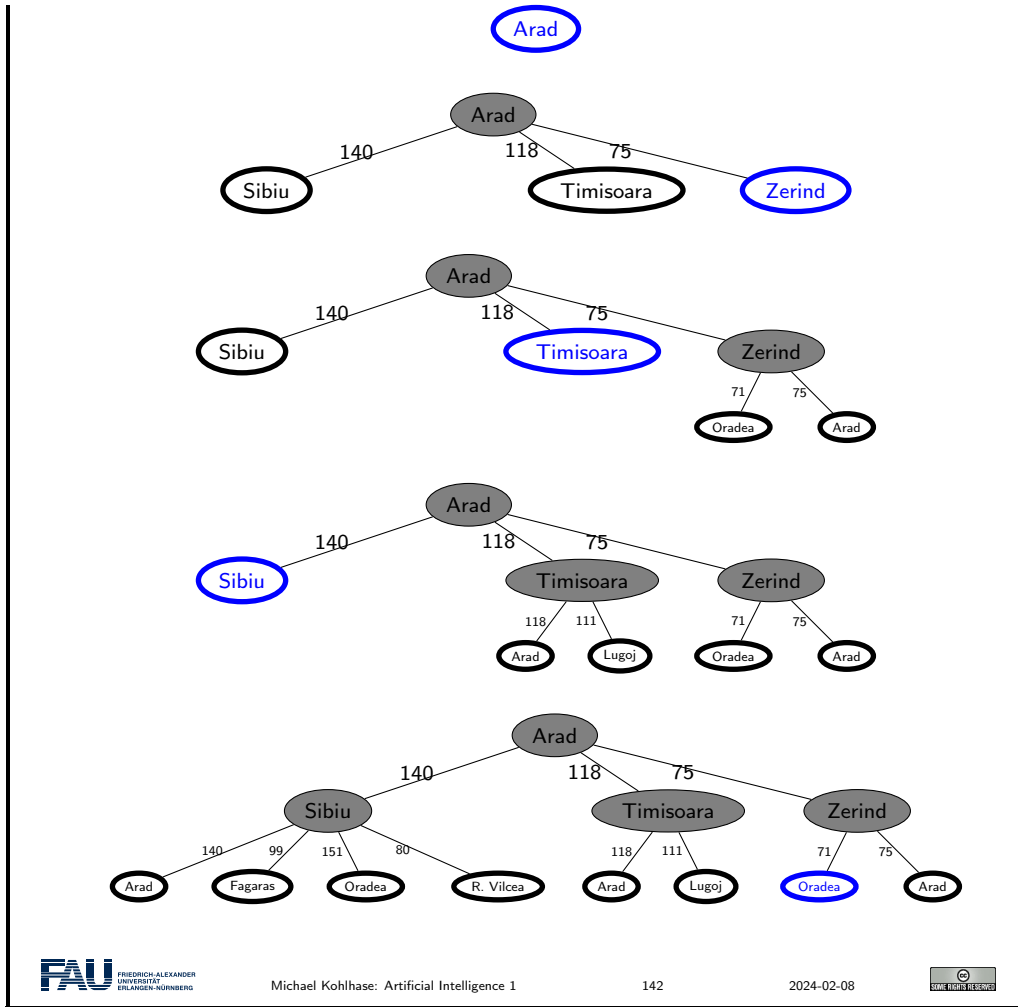

### Romania with Step Costs as Distances

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 141 2024-02-08

### Uniform-cost search

- ▷ **Idea:** Expand least cost unexpanded node.
- ▷ **Definition 6.4.4.** **Uniform-cost search (UCS)** is the strategy where the fringe is ordered by increasing path cost.
- ▷ **Note:** Equivalent to breadth first search if all step costs are equal.
- ▷ **Synthetic Example:**

Note that we must sum the distances to each leaf. That is, we go back to the first level after the third step.

### Uniform-cost search: Properties

|                  |                                                                   |
|------------------|-------------------------------------------------------------------|
| Completeness     | Yes (if step costs $\geq \epsilon > 0$ )                          |
| Time complexity  | number of nodes with path cost less than that of optimal solution |
| Space complexity | dito                                                              |
| Optimality       | Yes                                                               |

If step cost is negative, the same situation as in breadth first search can occur: later solutions may be cheaper than the current one.

If step cost is 0, one can run into infinite branches. UCS then degenerates into depth first search, the next kind of search algorithm we will encounter. Even if we have infinite branches, where the sum of step costs converges, we can get into trouble, since the search is forced down these infinite paths before a solution can be found.

Worst case is often worse than BFS, because large trees with small steps tend to be searched first. If step costs are uniform, it degenerates to BFS.

## 6.4.2 Depth-First Search Strategies

## Depth-first Search

- ▷ **Idea:** Expand deepest unexpanded node.
- ▷ **Definition 6.4.5.** Depth-first search (DFS) is the strategy where the fringe is organized as a (LIFO) stack i.e. successors go in at front of the fringe.
- ▷ **Definition 6.4.6.** Every node that is pushed to the stack is called a **backtrack point**. The action of popping a non-goal node from the stack and continuing the search with the new top element of the stack (a backtrack point by construction) is called **backtracking**, and correspondingly the DFS algorithm **backtracking search**.
- ▷ **Note:** Depth first search can perform infinite cyclic excursions  
Need a finite, non cyclic state space (or repeated state checking)

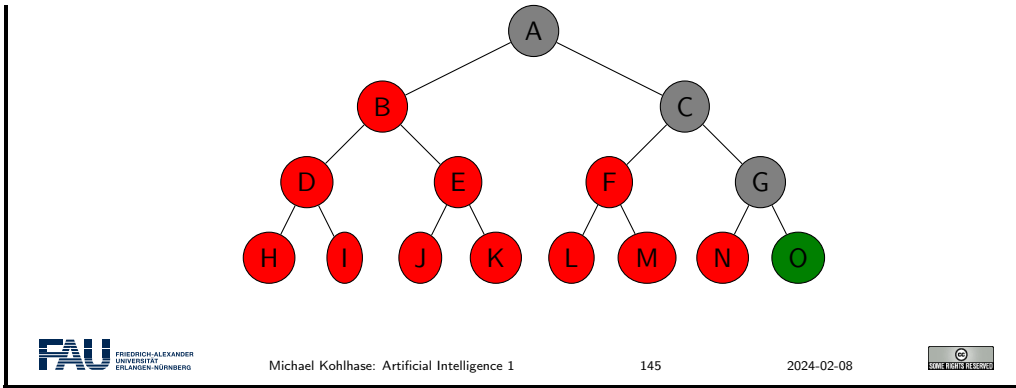

## Depth-First Search

- ▷ **Example 6.4.7 (Synthetic).**

### Depth-First Search: Romania

▷ Example 6.4.8 (Romania).

### Depth-first search: Properties

|                  |                                                                                                              |
|------------------|--------------------------------------------------------------------------------------------------------------|
| Completeness     | Yes: if state space finite<br>No: if search tree contains infinite paths or loops                            |
| Time complexity  | $\mathcal{O}(b^m)$<br>(we need to explore until max depth $m$ in any case!)                                  |
| Space complexity | $\mathcal{O}(bm)$ (i.e. linear space)<br>(need at most store $m$ levels and at each level at most $b$ nodes) |
| Optimality       | No (there can be many better solutions in the unexplored part of the search tree)                            |

▷ **Disadvantage:** Time terrible if  $m$  much larger than  $d$ .

▷ **Advantage:** Time may be much less than breadth first search if solutions are dense.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 147 2024-02-08

### Iterative deepening search

▷ **Definition 6.4.9.** Depth limited search is depth first search with a depth limit.

▷ **Definition 6.4.10.** Iterative deepening search (IDS) is depth limited search with ever increasing depth limits.

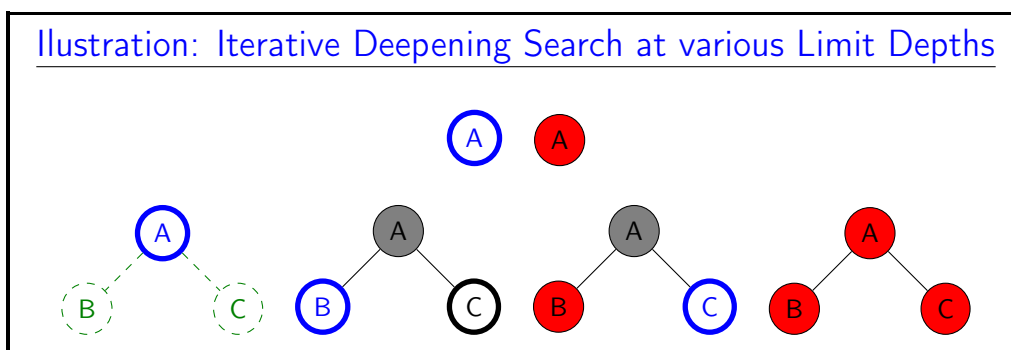

▷ **procedure** Tree\_Search (problem)

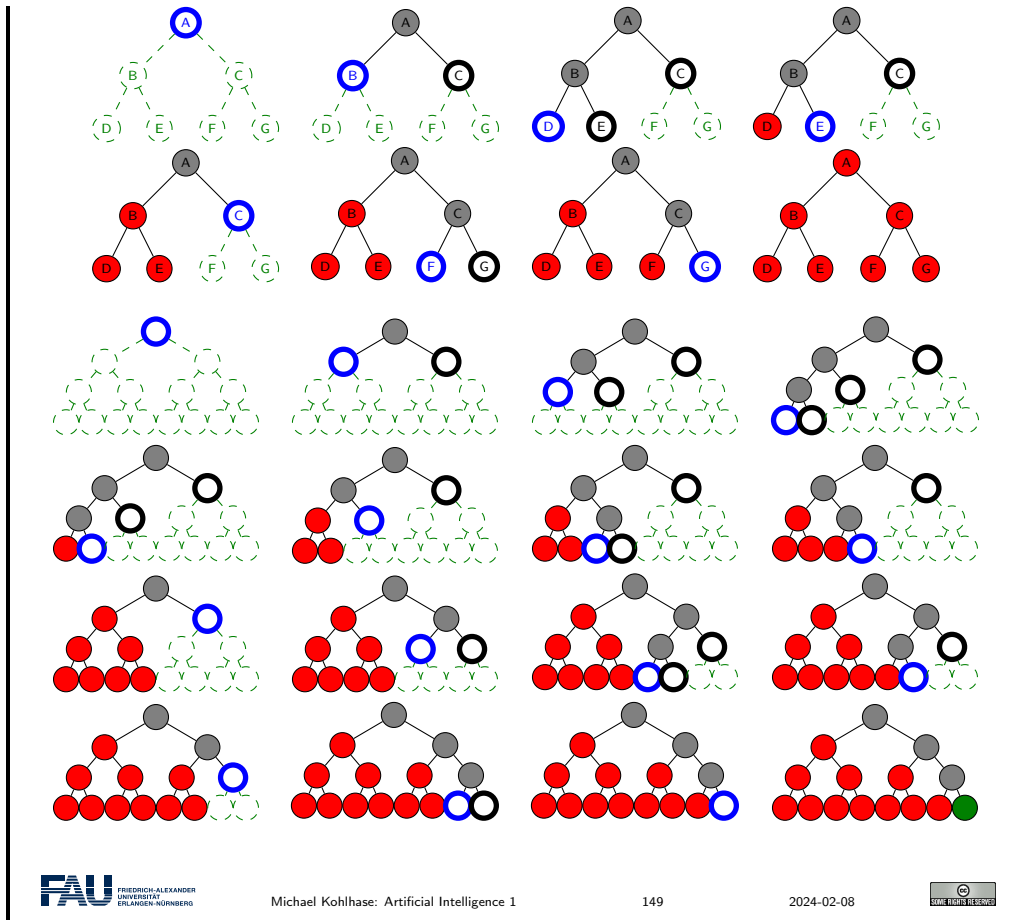

```

<initialize the search tree using the initial state of problem>
for depth = 0 to ∞
 result := Depth_Limited_search(problem,depth)
 if depth ≠ cutoff return result end if
end for
end procedure

```

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 148 2024-02-08

### Iterative deepening search: Properties

|                  |                                                                                          |
|------------------|------------------------------------------------------------------------------------------|
| Completeness     | Yes                                                                                      |
| Time complexity  | $(d+1) \cdot b^0 + d \cdot b^1 + (d-1) \cdot b^2 + \dots + b^d \in \mathcal{O}(b^{d+1})$ |
| Space complexity | $\mathcal{O}(b \cdot d)$                                                                 |
| Optimality       | Yes (if step cost = 1)                                                                   |

- ▷ **Consequence:** IDS used in practice for search spaces of large, infinite, or unknown depth.

**Note:** To find a solution (at depth  $d$ ) we have to search the whole tree up to  $d$ . Of course since we do not save the search state, we have to re-compute the upper part of the tree for the next level. This seems like a great waste of resources at first, however, IDS tries to be complete without the space penalties.

However, the space complexity is as good as DFS, since we are using DFS along the way. Like in BFS, the whole tree on level  $d$  (of optimal solution) is explored, so optimality is inherited from there. Like BFS, one can modify this to incorporate uniform cost search behavior.

As a consequence, variants of IDS are the method of choice if we do not have additional information.

### Comparison BFS (optimal) and IDS (not)

▷ **Example 6.4.11.** IDS may fail to be optimal at step sizes  $> 1$ .

Breadth first search

Iterative deepening search

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 151 2024-02-08

### 6.4.3 Further Topics

### Tree Search vs. Graph Search

- ▷ We have only covered **tree search algorithms**.
- ▷ **States** duplicated in **nodes** are a huge problem for **efficiency**.
- ▷ **Definition 6.4.12.** A **graph search algorithm** is a variant of a **tree search algorithm** that **prunes nodes** whose **state** has already been considered (**duplicate pruning**), essentially using a **DAG data structure**.
- ▷ **Observation 6.4.13.** **Tree search** is **memory intensive** it has to store the **fringe** so keeping a list of "explored states" does not lose much.
- ▷ **Graph versions** of all the **tree search algorithms** considered here exist, but are more difficult to understand (and to prove properties about).
- ▷ The (**time complexity**) properties are largely stable under **duplicate pruning**. (no gain in the worst case)
- ▷ **Definition 6.4.14.** We speak of a **search algorithm**, when we do not want to distinguish whether it is a **tree** or **graph search algorithm**. (**difference considered an implementation detail**)

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 152 2024-02-08

## Uninformed Search Summary

- ▷ **Tree/Graph Search Algorithms:** Systematically explore the state tree/graph induced by a **search problem** in search of a goal state. Search strategies only differ by the treatment of the fringe.
- ▷ **Search Strategies and their Properties:** We have discussed

| Criterion        | Breadth first           | Uniform cost                                 | Depth first | Iterative deepening |
|------------------|-------------------------|----------------------------------------------|-------------|---------------------|
| Completeness     | Yes <sup>1</sup>        | Yes <sup>2</sup>                             | No          | Yes                 |
| Time complexity  | $b^d$                   | $\approx b^d$                                | $b^m$       | $b^{d+1}$           |
| Space complexity | $b^d$                   | $\approx b^d$                                | $bm$        | $bd$                |
| Optimality       | Yes*                    | Yes                                          | No          | Yes*                |
| Conditions       | <sup>1</sup> $b$ finite | <sup>2</sup> $0 < \epsilon \leq \text{cost}$ |             |                     |

## Search Strategies; the XKCD Take

- ▷ **More Search Strategies?:** (from <https://xkcd.com/2407/>)

## 6.5 Informed Search Strategies

### Summary: Uninformed Search/Informed Search

- ▷ Problem formulation usually requires abstracting away real-world details to define

a **state space** that can feasibly be explored.

- ▷ Variety of **uninformed** search strategies.
- ▷ **Iterative deepening search** uses only **linear space** and not much more **time** than other **uninformed algorithms**.
- ▷ **Next Step:** Introduce additional knowledge about the problem (**heuristic search**)
  - ▷ Best-first-,  $A^*$ -strategies (guide the search by heuristics)
  - ▷ Iterative improvement **algorithms**.
- ▷ **Definition 6.5.1.** A **search algorithm** is called **informed**, iff it uses some form of external information – that is not part of the **search problem** – to guide the search.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 155 2024-02-08

### 6.5.1 Greedy Search

A **Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/22015>.

#### Best-first search

- ▷ **Idea:** Order the **fringe** by estimated “desirability” (Expand most desirable unexpanded node)
- ▷ **Definition 6.5.2.** An **evaluation function** assigns a **desirability** value to each **node** of the **search tree**.
- ▷ **Note:** A **evaluation function** is not part of the **search problem**, but must be added externally.
- ▷ **Definition 6.5.3.** In **best first search**, the **fringe** is a **queue** sorted in decreasing order of **desirability**.
- ▷ **Special cases:** Greedy search,  $A^*$  search

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 156 2024-02-08

This is like **UCS**, but with evaluation function related to problem at hand replacing the **path cost** function.

If the **heuristic** is arbitrary, we expect incompleteness!

Depends on how we measure “desirability”.

Concrete examples follow.

#### Greedy search

- ▷ **Idea:** Expand the **node** that *appears* to be closest to the **goal**.
- ▷ **Definition 6.5.4.** A **heuristic** is an **evaluation function**  $h$  on **states** that estimates the **cost** from  $n$  to the nearest **goal state**. We speak of **heuristic search** if the **search algorithm** uses a **heuristic** in some way.
- ▷ **Note:** All **nodes** for the same **state** must have the same  $h$ -value!

▷ **Definition 6.5.5.** Given a heuristic  $h$ , greedy search is the strategy where the fringe is organized as a queue sorted by increasing  $h$  value.

▷ **Example 6.5.6.** Straight-line distance from/to Bucharest.

▷ **Note:** Unlike uniform cost search the node evaluation function has nothing to do with the nodes expanded so far

internal search control  $\rightsquigarrow$  external search control  
 partial solution cost  $\rightsquigarrow$  goal cost estimation

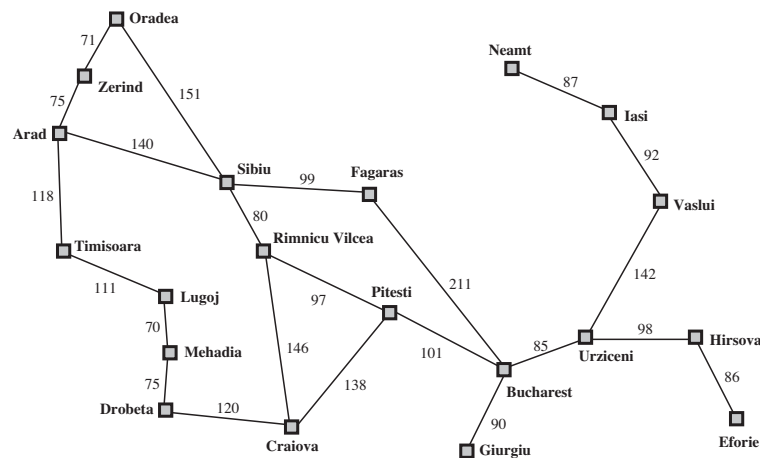

In greedy search we replace the objective cost to construct the current solution with a heuristic or subjective measure from which we think it gives a good idea how far we are from a solution. Two things have shifted:

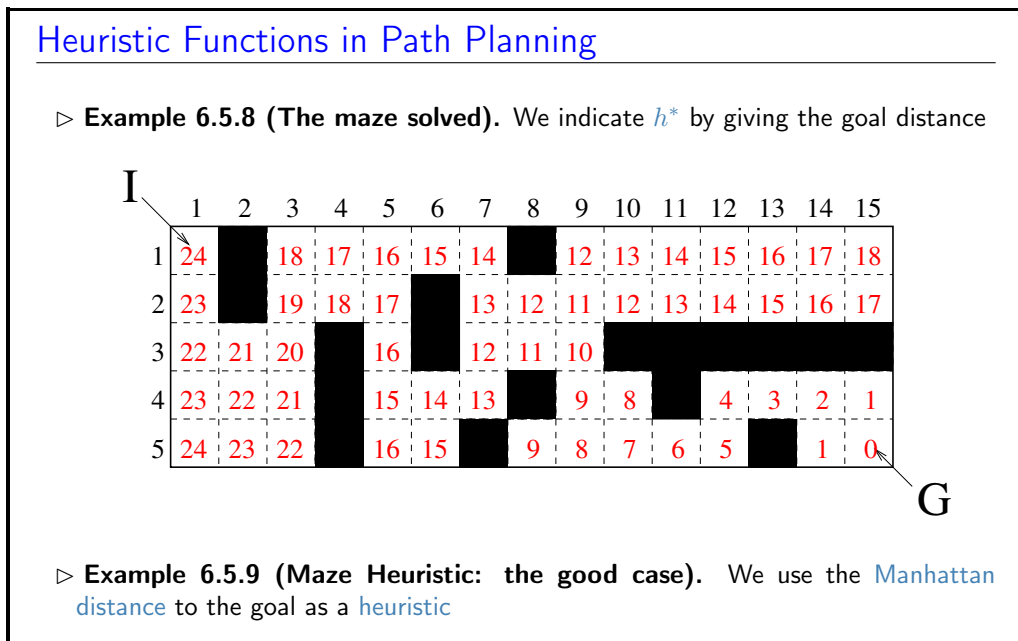

- we went from internal (determined only by features inherent in the search space) to an external/heuristic cost
- instead of measuring the cost to build the current partial solution, we estimate how far we are from the desired goal

## Romania with Straight-Line Distances

▷ **Example 6.5.7 (Informed Travel).**  $h_{\text{SLD}}(n)$  = straight – line distance to Bucharest

|         |     |                |     |           |     |          |     |
|---------|-----|----------------|-----|-----------|-----|----------|-----|
| Arad    | 366 | Mehadia        | 241 | Bucharest | 0   | Neamt    | 234 |
| Craiova | 160 | Oradea         | 380 | Drobeta   | 242 | Pitesti  | 100 |
| Eforie  | 161 | Rimnicu Vilcea | 193 | Fagaras   | 176 | Sibiu    | 253 |
| Giurgiu | 77  | Timisoara      | 329 | Hirsova   | 151 | Urziceni | 80  |
| Iasi    | 226 | Vaslui         | 199 | Lugoj     | 244 | Zerind   | 374 |

▷ **Example 6.5.10 (Maze Heuristic: the bad case).** We use the Manhattan distance to the goal as a heuristic again

### Greedy search: Properties

|                  |                                                                                     |
|------------------|-------------------------------------------------------------------------------------|
| Completeness     | No: Can get stuck in loops<br>Complete in finite space with repeated state checking |
| Time complexity  | $\mathcal{O}(b^m)$                                                                  |
| Space complexity | $\mathcal{O}(b^m)$                                                                  |
| Optimality       | No                                                                                  |

▷ **Example 6.5.11.** Greedy search can get stuck going from Iasi to Oradea:  
Iasi → Neamt → Iasi → Neamt → ...

- ▷ **Worst-case Time:** Same as **depth first search**.
- ▷ **Worst-case Space:** Same as **breadth first search**.
- ▷ **But:** A good **heuristic** can give dramatic improvements.

*Remark 6.5.12.* **Greedy search** is similar to **UCS**. Unlike the latter, the node **evaluation function** has nothing to do with the **nodes** explored so far. This can prevent nodes from being enumerated systematically as they are in **UCS** and **BFS**.

For completeness, we need repeated state checking as the example shows. This enforces complete **enumeration** of the **state space** (provided that it is **finite**), and thus gives us completeness.

Note that nothing prevents from *all* nodes being searched in worst case; e.g. if the **heuristic function** gives us the same (low) estimate on all nodes except where the **heuristic** mis-estimates the distance to be high. So in the worst case, greedy search is even worse than **BFS**, where  $d$  (depth of first solution) replaces  $m$ .

The search procedure cannot be optimal, since actual cost of solution is not considered.

For both, **completeness** and **optimality**, therefore, it is necessary to take the actual cost of partial solutions, i.e. the **path cost**, into account. This way, paths that are known to be expensive are avoided.

## 6.5.2 Heuristics and their Properties

A **Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/22019>.

### Heuristic Functions

- ▷ **Definition 6.5.13.** Let  $\Pi$  be a **search problem** with **states**  $\mathcal{S}$ . A **heuristic function** (or short **heuristic**) for  $\Pi$  is a **function**  $h: \mathcal{S} \rightarrow \mathbb{R}_0^+ \cup \{\infty\}$  so that  $h(s) = 0$  whenever  $s$  is a **goal state**.
- ▷  $h(s)$  is intended as an estimate the distance between **state**  $s$  and the nearest **goal state**.
- ▷ **Definition 6.5.14.** Let  $\Pi$  be a **search problem** with **states**  $\mathcal{S}$ , then the **function**  $h^*: \mathcal{S} \rightarrow \mathbb{R}_0^+ \cup \{\infty\}$ , where  $h^*(s)$  is the **cost** of a cheapest **path** from  $s$  to a **goal state**, or  $\infty$  if no such **path** exists, is called the **goal distance function** for  $\Pi$ .
- ▷ **Notes:**
  - ▷  $h(s) = 0$  on **goal states**: If your estimator returns “I think it’s still a long way” on a **goal state**, then its **intelligence** is, um . . .
  - ▷ Return **value**  $\infty$ : To indicate dead ends, from which the **goal state** can’t be reached anymore.
  - ▷ The distance estimate depends only on the **state**  $s$ , not on the **node** (i.e., the **path** we took to reach  $s$ ).

Where does the word “Heuristic” come from?

- ▷ Ancient Greek word  $\epsilon\upsilon\rho\iota\sigma\kappa\epsilon\iota\nu$  ( $\hat{=}$  “I find”) (aka.  $\epsilon\upsilon\rho\epsilon\kappa\alpha!$ )
- ▷ Popularized in modern science by George Polya: “How to solve it” [Pól73]
- ▷ same word often used for “rule of thumb” or “imprecise solution method”.

## Heuristic Functions: The Eternal Trade-Off

- ▷ “Distance Estimate”? ( $h$  is an arbitrary function in principle)
  - ▷ In practice, we want it to be *accurate* (aka: *informative*), i.e., close to the actual goal distance.
  - ▷ We also want it to be fast, i.e., a small overhead for computing  $h$ .
  - ▷ These two wishes are in contradiction!
- ▷ **Example 6.5.15 (Extreme cases).**
  - ▷  $h = 0$ : no overhead at all, completely un-informative.
  - ▷  $h = h^*$ : perfectly accurate, overhead  $\hat{=}$  solving the problem in the first place.
- ▷ **Observation 6.5.16.** *We need to trade off the accuracy of  $h$  against the overhead for computing it.*

## Properties of Heuristic Functions

- ▷ **Definition 6.5.17.** Let  $\Pi$  be a search problem with states  $S$  and actions  $A$ . We say that a heuristic  $h$  for  $\Pi$  is **admissible** if  $h(s) \leq h^*(s)$  for all  $s \in S$ . We say that  $h$  is **consistent** if  $h(s) - h(s') \leq c(a)$  for all  $s \in S$ ,  $a \in A$ , and  $s' \in \mathcal{T}(s, a)$ .
- ▷ **In other words . . . :**
  - ▷  $h$  is **admissible** if it is a **lower bound** on goal distance.
  - ▷  $h$  is **consistent** if, when applying an **action**  $a$ , the **heuristic value** cannot decrease by more than the cost of  $a$ .

## Properties of Heuristic Functions, ctd.

- ▷ Let  $\Pi$  be a problem, and let  $h$  be a heuristic for  $\Pi$ . If  $h$  is **consistent**, then  $h$  is **admissible**.
- ▷ *Proof:* we prove  $h(s) \leq h^*(s)$  for all  $s \in S$  by **induction** over the **length** of the cheapest **path** to a **goal node**.
  1. **base case**

- 1.1.  $h(s) = 0$  by definition of heuristic, so  $h(s) \leq h^*(s)$  as desired.
2. step case
  - 2.1. We assume that  $h(s') \leq h^*(s)$  for all states  $s'$  with a cheapest goal node path of length  $n$ .
  - 2.2. Let  $s$  be a state whose cheapest goal path has length  $n+1$  and the first transition is  $o = (s, s')$ .
  - 2.3. By consistency, we have  $h(s) - h(s') \leq c(o)$  and thus  $h(s) \leq h(s') + c(o)$ .
  - 2.4. By construction,  $h^*(s)$  has a cheapest goal path of length  $n$  and thus, by induction hypothesis  $h(s') \leq h^*(s')$ .
  - 2.5. By construction,  $h^*(s) = h^*(s') + c(o)$ .
  - 2.6. Together this gives us  $h(s) \leq h^*(s)$  as desired.

▷ Consistency is a sufficient condition for admissibility (easier to check)

## Properties of Heuristic Functions: Examples

- ▷ **Example 6.5.18.** Straight line distance is admissible and consistent by the triangle inequality.  
If you drive 100km, then the straight line distance to Rome can't decrease by more than 100km.
- ▷ **Observation:** In practice, admissible heuristics are typically consistent.
- ▷ **Example 6.5.19 (An admissible, but inconsistent heuristic).** When traveling to Rome, let  $h(\text{Munich}) = 300$  and  $h(\text{Innsbruck}) = 100$ .
- ▷ **Inadmissible heuristics** typically arise as approximations of admissible heuristics that are too costly to compute. (see later)

### 6.5.3 A-Star Search

A Video Nugget covering this subsection can be found at <https://fau.tv/clip/id/22020>.

## A\* Search: Evaluation Function

- ▷ **Idea:** Avoid expanding paths that are already expensive (make use of actual cost)  
The simplest way to combine heuristic and path cost is to simply add them.
- ▷ **Definition 6.5.20.** The evaluation function for A\* search is given by  $f(n) = g(n) + h(n)$ , where  $g(n)$  is the path cost for  $n$  and  $h(n)$  is the estimated cost to the nearest goal from  $n$ .
- ▷ Thus  $f(n)$  is the estimated total cost of the path through  $n$  to a goal.
- ▷ **Definition 6.5.21.** Best first search with evaluation function  $g + h$  is called A\* search.

This works, provided that  $h$  does not overestimate the true cost to achieve the goal. In other words,  $h$  must be *optimistic* wrt. the real cost  $h^*$ . If we are too pessimistic, then non-optimal solutions have a chance.

### A\* Search: Optimality

▷ **Theorem 6.5.22.** *A\* search with admissible heuristic is optimal.*

▷ *Proof:* We show that sub-optimal nodes are never expanded by A\*

1. Suppose a suboptimal goal node  $G$  has been generated then we are in the following situation:

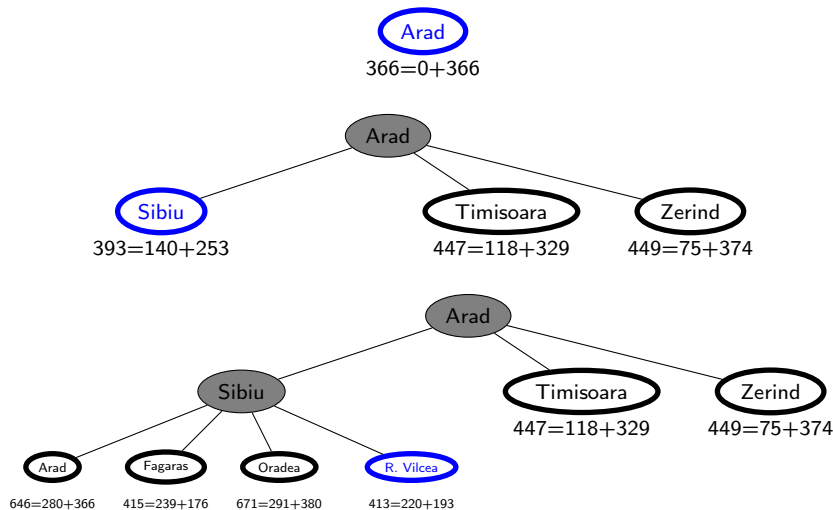

2. Let  $n$  be an unexpanded node on a path to an optimality goal node  $O$ , then

|                                  |                         |
|----------------------------------|-------------------------|
| $f(G) = g(G)$                    | since $h(G) = 0$        |
| $g(G) > g(O)$                    | since $G$ suboptimal    |
| $g(O) = g(n) + h^*(n)$           | $n$ on optimal path     |
| $g(n) + h^*(n) \geq g(n) + h(n)$ | since $h$ is admissible |
| $g(n) + h(n) = f(n)$             |                         |

3. Thus,  $f(G) > f(n)$  and A\* never expands  $G$ .

### A\* Search Example

We will find a solution with little search.

### Additional Observations (Not Limited to Path Planning)

▷ Example 6.5.24 ( $A^*$  ( $g + h$ ), “good case”).

- ▷ In  $A^*$  with a consistent heuristic,  $g + h$  always increases monotonically ( $h$  cannot decrease more than  $g$  increases)
- ▷ We need more search, in the “right upper half”. This is typical: Greedy best first search tends to be faster than  $A^*$ .

### Additional Observations (Not Limited to Path Planning)

▷ Example 6.5.25 (Greedy best-first search, “bad case”).

Search will be mis-guided into the “dead-end street”.

### Additional Observations (Not Limited to Path Planning)

▷ Example 6.5.26 ( $A^*$  ( $g + h$ ), “bad case”).

We will search less of the “dead-end street”. Sometimes  $g + h$  gives better search guidance than  $h$ . ( $\leadsto A^*$  is faster there)

### Additional Observations (Not Limited to Path Planning)

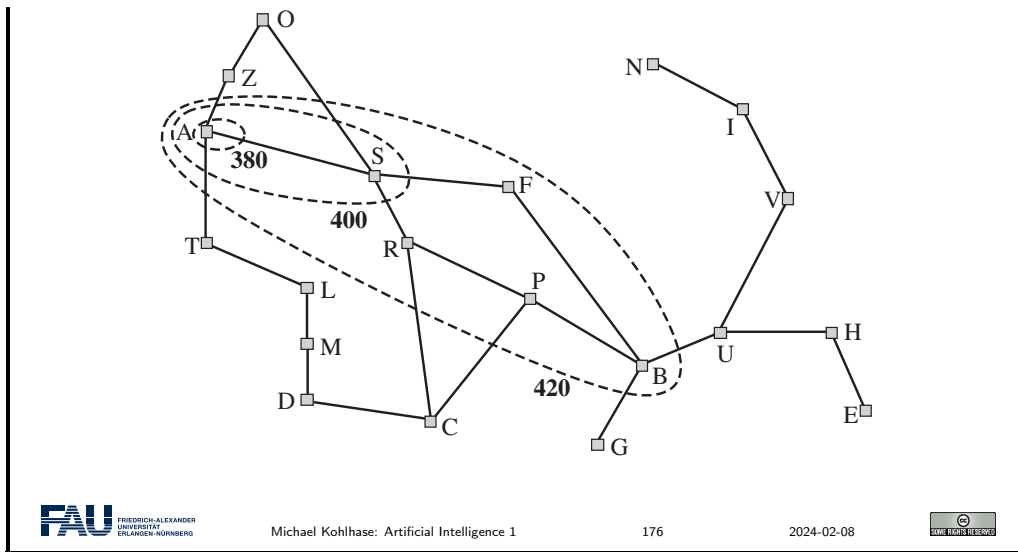

▷ Example 6.5.27 ( $A^*$  ( $g + h$ ) using  $h^*$ ).

In  $A^*$ , node values always increase monotonically (with any heuristic). If the heuristic is perfect, they remain constant on optimal paths.

### $A^*$ search: $f$ -contours

▷  $A^*$  gradually adds “ $f$ -contours” of nodes

### A\* search: Properties

▷ Properties of A\*

|                  |                                                                         |
|------------------|-------------------------------------------------------------------------|
| Completeness     | Yes (unless there are infinitely many nodes $n$ with $f(n) \leq f(0)$ ) |
| Time complexity  | Exponential in [relative error in $h \times$ length of solution]        |
| Space complexity | Same as time (variant of BFS)                                           |
| Optimality       | Yes                                                                     |

▷ A\* expands all (some/no) nodes with  $f(n) < h^*(n)$

▷ The run-time depends on how well we approximated the real cost  $h^*$  with  $h$ .

### 6.5.4 Finding Good Heuristics

A Video Nugget covering this subsection can be found at <https://fau.tv/clip/id/22021>.

Since the availability of admissible heuristics is so important for informed search (particularly for A\*), let us see how such heuristics can be obtained in practice. We will look at an example, and then derive a general procedure from that.

### Admissible heuristics: Example 8-puzzle

Start State

Goal State

- ▷ **Example 6.5.28.** Let  $h_1(n)$  be the number of misplaced tiles in node  $n$ .  
( $h_1(S) = 9$ )
- ▷ **Example 6.5.29.** Let  $h_2(n)$  be the total Manhattan distance from desired location of each tile.  
( $h_2(S) = 3 + 1 + 2 + 2 + 2 + 3 + 2 + 2 + 3 = 20$ )
- ▷ **Observation 6.5.30 (Typical search costs).** ( $IDS \hat{=} \text{iterative deepening search}$ )

| nodes explored | IDS       | $A^*(h_1)$ | $A^*(h_2)$ |
|----------------|-----------|------------|------------|
| $d = 14$       | 3,473,941 | 539        | 113        |
| $d = 24$       | too many  | 39,135     | 1,641      |

## Dominance

- ▷ **Definition 6.5.31.** Let  $h_1$  and  $h_2$  be two admissible heuristics we say that  $h_2$  dominates  $h_1$  if  $h_2(n) \geq h_1(n)$  for all  $n$ .
- ▷ **Theorem 6.5.32.** If  $h_2$  dominates  $h_1$ , then  $h_2$  is better for search than  $h_1$ .

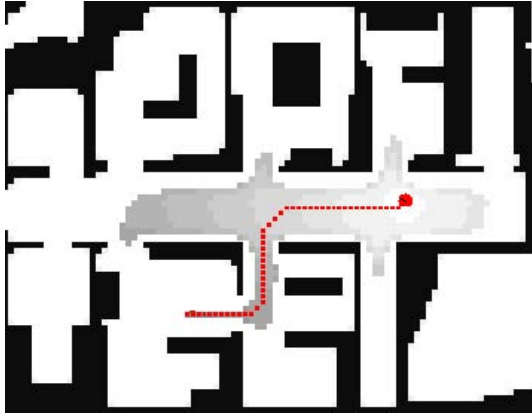

## Relaxed problems

- ▷ **Observation:** Finding good admissible heuristics is an art!
- ▷ **Idea:** Admissible heuristics can be derived from the exact solution cost of a relaxed version of the problem.
- ▷ **Example 6.5.33.** If the rules of the 8-puzzle are relaxed so that a tile can move anywhere, then we get heuristic  $h_1$ .
- ▷ **Example 6.5.34.** If the rules are relaxed so that a tile can move to any adjacent square, then we get heuristic  $h_2$ . (Manhattan distance)
- ▷ **Definition 6.5.35.** Let  $\Pi := \langle S, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$  be a search problem, then we call a search problem  $\mathcal{P}^r := \langle S, \mathcal{A}^r, \mathcal{T}^r, \mathcal{I}^r, \mathcal{G}^r \rangle$  a relaxed problem (wrt.  $\Pi$ ; or simply relaxation of  $\Pi$ ), iff  $\mathcal{A} \subseteq \mathcal{A}^r$ ,  $\mathcal{T} \subseteq \mathcal{T}^r$ ,  $\mathcal{I} \subseteq \mathcal{I}^r$ , and  $\mathcal{G} \subseteq \mathcal{G}^r$ .
- ▷ **Lemma 6.5.36.** If  $\mathcal{P}^r$  relaxes  $\Pi$ , then every solution for  $\Pi$  is one for  $\mathcal{P}^r$ .
- ▷ **Key point:** The optimal solution cost of a relaxed problem is not greater than the optimal solution cost of the real problem.

Relaxation means to remove some of the constraints or requirements of the original problem, so that a solution becomes easy to find. Then the cost of this easy solution can be used as an optimistic approximation of the problem.

### Empirical Performance: $A^*$ in Path Planning

▷ **Example 6.5.37 (Live Demo vs. Breadth-First Search).**

See <http://qiao.github.io/PathFinding.js/visual/>

▷ **Difference to Breadth-first Search?:** That would explore all grid cells in a *circle* around the initial state!

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 181 2024-02-08 

## 6.6 Local Search

**Video Nuggets** covering this section can be found at <https://fau.tv/clip/id/22050> and <https://fau.tv/clip/id/22051>.

### Systematic Search vs. Local Search

▷ **Definition 6.6.1.** We call a **search algorithm systematic**, if it considers all **states** at some point.

▷ **Example 6.6.2.**  
All **tree search algorithms** (except pure **depth first search**) are **systematic**. (given **reasonable assumptions e.g. about costs**.)

▷ **Observation 6.6.3.** *Systematic search algorithms are complete.*

▷ **Observation 6.6.4.** *In systematic search algorithms there is no limit of the number of nodes that are kept in memory at any time.*

▷ **Alternative:** Keep only one (or a few) **nodes** at a time

▷  $\rightsquigarrow$  no **systematic** exploration of all options,  $\rightsquigarrow$  **incomplete**.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 182 2024-02-08 

## Local Search Problems

- ▷ **Idea:** Sometimes the **path** to the **solution** is irrelevant.
  - ▷ **Example 6.6.5 (8 Queens Problem).** Place 8 **queens** on a **chess board**, so that no two **queens** threaten each other.
  - ▷ This problem has various solutions (the one of the right isn't one of them)
  - ▷ **Definition 6.6.6.** A **local search algorithm** is a **search algorithm** that operates on a single **state**, the **current state** (rather than multiple **paths**).  
(**advantage:** constant space)
- ▷ Typically **local search algorithms** only move to **successor** of the **current state**, and do not retain search **paths**.
- ▷ Applications include: integrated circuit design, factory-floor layout, job-shop scheduling, portfolio management, fleet deployment,...

## Local Search: Iterative improvement algorithms

- ▷ **Definition 6.6.7.** The **traveling salesman problem (TSP)** is to find shortest trip through set of cities such that each city is visited exactly once.
- ▷ **Idea:** Start with any complete tour, perform pairwise exchanges

- ▷ **Definition 6.6.8.** The  **$n$ -queens problem** is to put  $n$  **queens** on  $n \times n$  board such that no two **queen** in the same row, columns, or diagonal.
- ▷ **Idea:** Move a **queen** to reduce number of conflicts

## Hill-climbing (gradient ascent/descent)

- ▷ **Idea:** Start anywhere and go in the direction of the steepest ascent.
- ▷ **Definition 6.6.9.** **Hill climbing** (also **gradient ascent**) is a **local search algorithm**

that iteratively selects the best **successor**:

```

procedure Hill-Climbing (problem) /* a state that is a local minimum */
 local current, neighbor /* nodes */
 current := Make-Node(Initial-State[problem])
 loop
 neighbor := <a highest-valued successor of current>
 if Value[neighbor] < Value[current] return [current] end if
 current := neighbor
 end loop
end procedure

```

- ▷ **Intuition:** Like **best first search** without memory.
- ▷ Works, if solutions are dense and **local maxima** can be escaped.

In order to understand the procedure on a more intuitive level, let us consider the following scenario: We are in a dark landscape (or we are blind), and we want to find the highest hill. The search procedure above tells us to start our search anywhere, and for every step first feel around, and then take a step into the direction with the steepest ascent. If we reach a place, where the next step would take us down, we are finished.

Of course, this will only get us into **local maxima**, and has no guarantee of getting us into **global ones** (remember, we are blind). The solution to this problem is to re-start the search at random (we do not have any information) places, and hope that one of the random jumps will get us to a slope that leads to a global maximum.

### Example Hill Climbing with 8 Queens

- ▷ **Idea:** Consider  $h \hat{=}$  number of queens that threaten each other.
- ▷ **Example 6.6.10.** An 8-queens state with heuristic cost estimate  $h = 17$  showing  $h$ -values for moving a queen within its column:
- ▷ **Problem:** The state space has **local minima**. e.g. the board on the right has  $h = 1$  but every **successor** has  $h > 1$ .

|    |    |    |    |    |    |    |    |
|----|----|----|----|----|----|----|----|
| 18 | 12 | 14 | 13 | 13 | 12 | 14 | 14 |
| 14 | 16 | 13 | 15 | 12 | 14 | 12 | 16 |
| 14 | 12 | 18 | 13 | 15 | 12 | 14 | 14 |
| 15 | 14 | 14 | 13 | 16 | 13 | 16 | 16 |
| 17 | 14 | 17 | 15 | 14 | 16 | 16 | 16 |
| 17 | 16 | 18 | 15 | 15 | 15 | 15 | 15 |
| 18 | 14 | 16 | 15 | 15 | 14 | 16 | 16 |
| 14 | 14 | 13 | 17 | 12 | 14 | 12 | 18 |

### Hill-climbing

- ▷ **Problem:** Depending on **initial state**, can get stuck on **local maxima/minima** and plateaux.
- ▷ “Hill-climbing search is like climbing Everest in thick fog with amnesia”.
- ▷ **Idea:** Escape **local maxima** by allowing some “bad” or random moves.
- ▷ **Example 6.6.11.** **local search, simulated annealing, ...**
- ▷ **Properties:** All are **incomplete, nonoptimal**.
- ▷ Sometimes performs well in practice (if (optimal) solutions are dense)

FRIEDRICH-ALEXANDER  
UNIVERSITÄT  
ERLANGEN-NÜRNBERG

Michael Kohlhase: Artificial Intelligence 1

187

2024-02-08

Recent work on **hill climbing algorithms** tries to combine complete search with randomization to escape certain odd phenomena occurring in statistical distribution of solutions.

### Simulated annealing (Idea)

- ▷ **Definition 6.6.12.** **Ridges** are ascending successions of **local maxima**.
- ▷ **Problem:** They are extremely difficult to be navigated for **local search algorithms**.
- ▷ **Idea:** Escape **local maxima** by allowing some “bad” moves, but gradually decrease their size and frequency.

- ▷ Annealing is the process of heating steel and let it cool gradually to give it time to grow an optimal crystal structure.
- ▷ **Simulated annealing** is like shaking a ping pong ball occasionally on a bumpy surface to free it. (so it does not get stuck)
- ▷ Devised by Metropolis et al for physical process modelling [Met+53]
- ▷ Widely used in VLSI layout, airline scheduling, etc.

### Simulated annealing (Implementation)

- ▷ **Definition 6.6.13.** The following **algorithm** is called **simulated annealing**:

```

procedure Simulated-Annealing (problem,schedule) /* a solution state */
 local node, next /* nodes */

```

```

local T /* a "temperature" controlling prob. of downward steps */
current := Make-Node(Initial-State[problem])
for t := 1 to ∞
 T := schedule[t]
 if T = 0 return current end if
 next := <a randomly selected successor of current>
 Δ(E) := Value[next] - Value[current]
 if Δ(E) > 0 current := next
 else
 current := next <only with probability> eΔ(E)/T
 end if
end for
end procedure

```

A **schedule** is a mapping from time to "temperature".

## Properties of simulated annealing

- ▷ At fixed "temperature"  $T$ , state occupation probability reaches Boltzman distribution

$$p(x) = \alpha e^{-\frac{E(x)}{kT}}$$

$T$  decreased slowly enough  $\leadsto$  always reach best state  $x^*$  because

$$\frac{e^{-\frac{E(x^*)}{kT}}}{e^{-\frac{E(x)}{kT}}} = e^{\frac{E(x^*) - E(x)}{kT}} \gg 1$$

for small  $T$ .

- ▷ **Question:** Is this necessarily an interesting guarantee?

## Local beam search

- ▷ **Definition 6.6.14.** **Local beam search** is a search algorithm that keep  $k$  states instead of 1 and chooses the top  $k$  of all their successors.
- ▷ **Observation:** Local beam search is not the same as  $k$  searches run in parallel! (Searches that find good states recruit other searches to join them)
- ▷ **Problem:** Quite often, all  $k$  searches end up on the same local hill!
- ▷ **Idea:** Choose  $k$  successors randomly, biased towards good ones. (Observe the close analogy to natural selection!)

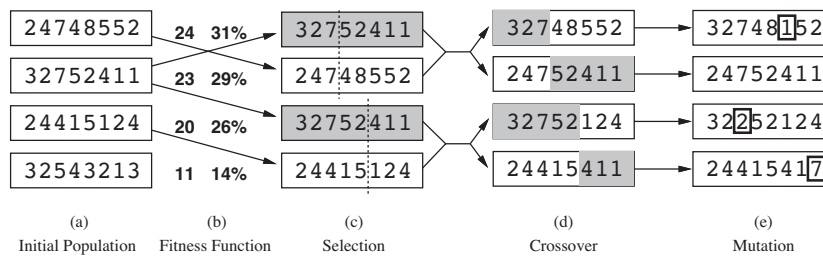

### Genetic algorithms (very briefly)

▷ **Definition 6.6.15.** A **genetic algorithm** is a variant of **local beam search** that generates **successors** by

- ▷ randomly modifying **states** (**mutation**)
- ▷ mixing **pairs** of **states** (**sexual reproduction** or **crossover**)

to optimize a fitness function. (survival of the fittest)

▷ **Example 6.6.16.** Generating **successors** for **8 queens**

### Genetic algorithms (continued)

▷ **Problem:** Genetic algorithms require **states** encoded as **strings**.

▷ **Crossover** only helps iff **substrings** are meaningful components.

▷ **Example 6.6.17 (Evolving 8 Queens).** First **crossover**

▷ **Note:** Genetic algorithms  $\neq$  evolution: e.g., real genes also encode replication machinery!

# Chapter 7

## Adversarial Search for Game Playing

A **Video Nugget** covering this chapter can be found at <https://fau.tv/clip/id/22079>.

### 7.1 Introduction

**Video Nuggets** covering this section can be found at <https://fau.tv/clip/id/22060> and <https://fau.tv/clip/id/22061>.

#### The Problem

- ▷ **The Problem of Game-Play:** cf. chapter 6
- ▷ **Example 7.1.1.**

- ▷ **Definition 7.1.2.** **Adversarial search**  $\hat{=}$  Game playing against an opponent.

#### Why Game Playing?

- ▷ What do **you** think?

- ▷ Playing a game well clearly requires a form of “intelligence”.
- ▷ Games capture a pure form of competition between opponents.
- ▷ Games are abstract and precisely defined, thus very easy to formalize.
- ▷ Game playing is one of the oldest sub-areas of AI (ca. 1950).
- ▷ The dream of a machine that plays chess is, indeed, *much* older than AI!

“Schachtürke” (1769)

“El Ajedrecista” (1912)

## “Game” Playing? Which Games?

- ▷ ... sorry, we're not gonna do soccer here.
- ▷ **Definition 7.1.3 (Restrictions).** A game in the sense of AI-1 is one where
  - ▷ Game state discrete, number of game state finite.
  - ▷ Finite number of possible moves.
  - ▷ The game state is fully observable.
  - ▷ The outcome of each move is deterministic.
  - ▷ Two players: Max and Min.
  - ▷ Turn-taking: It's each player's turn alternatingly. Max begins.
  - ▷ Terminal game states have a utility  $u$ . Max tries to maximize  $u$ , Min tries to minimize  $u$ .
  - ▷ In that sense, the utility for Min is the exact opposite of the utility for Max (“zero sum”).
  - ▷ There are no infinite runs of the game (no matter what moves are chosen, a terminal state is reached after a finite number of moves).

## An Example Game

- ▷ Game states: Positions of figures.
- ▷ Moves: Given by rules.
- ▷ Players: White (**Max**), Black (**Min**).
- ▷ Terminal states: Checkmate.
- ▷ Utility of terminal states, e.g.:
  - ▷ +100 if Black is checkmated.
  - ▷ 0 if stalemate.
  - ▷ -100 if White is checkmated.

## “Game” Playing? Which Games Not?

- ▷ Soccer (sorry guys; not even RoboCup)
- ▷ Important types of games that we **don't** tackle here:
  - ▷ Chance. (E.g., backgammon)
  - ▷ More than two players. (E.g., Halma)
  - ▷ Hidden information. (E.g., most card games)
  - ▷ Simultaneous moves. (E.g., Diplomacy)
  - ▷ Not zero-sum, i.e., outcomes may be beneficial (or detrimental) for both players. (cf. Game theory: Auctions, elections, economy, politics, ...)
- ▷ Many of these more general game types can be handled by similar/extended algorithms.

## (A Brief Note On) Formalization

- ▷ **Definition 7.1.4.** An **adversarial search problem** is a search problem  $\langle \mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$ , where
  1.  $\mathcal{S} = \mathcal{S}^{\text{Max}} \uplus \mathcal{S}^{\text{Min}} \uplus \mathcal{G}$  and  $\mathcal{A} = \mathcal{A}^{\text{Max}} \uplus \mathcal{A}^{\text{Min}}$
  2. For  $a \in \mathcal{A}^{\text{Max}}$ , if  $s \xrightarrow{a} s'$  then  $s \in \mathcal{S}^{\text{Max}}$  and  $s' \in (\mathcal{S}^{\text{Min}} \cup \mathcal{G})$ .
  3. For  $a \in \mathcal{A}^{\text{Min}}$ , if  $s \xrightarrow{a} s'$  then  $s \in \mathcal{S}^{\text{Min}}$  and  $s' \in (\mathcal{S}^{\text{Max}} \cup \mathcal{G})$ .
 together with a **game utility function**  $u: \mathcal{G} \rightarrow \mathbb{R}$ . (the “score” of the game)
- ▷ **Definition 7.1.5 (Commonly used terminology).**  
**position**  $\hat{=}$  **state**, **move**  $\hat{=}$  **action**, **end state**  $\hat{=}$  **terminal state**  $\hat{=}$  **goal state**.
- ▷ **Remark:** A round of the game – one move **Max**, one move **Min** – is often referred to as a “move”, and individual **actions** as “half-moves” (we *don't* in AI-1)

## Why Games are Hard to Solve: I

- ▷ What is a “solution” here?
- ▷ **Definition 7.1.6.** Let  $\Theta$  be an adversarial search problem, and let  $X \in \{\text{Max}, \text{Min}\}$ . A strategy for  $X$  is a function  $\sigma^X : \mathcal{S}^X \rightarrow \mathcal{A}^X$  so that  $a$  is applicable to  $s$  whenever  $\sigma^X(s) = a$ .
- ▷ We don't know how the opponent will react, and need to prepare for all possibilities.
- ▷ **Definition 7.1.7.** A strategy is called optimal if it yields the best possible utility for  $X$  assuming perfect opponent play (not formalized here).
- ▷ **Problem:** In (almost) all games, computing a strategy is infeasible.
- ▷ **Solution:** Compute the next move “on demand”, given the current state instead.

## Why Games are hard to solve II

- ▷ **Example 7.1.8.** Number of reachable states in chess:  $10^{40}$ .
- ▷ **Example 7.1.9.** Number of reachable states in go:  $10^{100}$ .
- ▷ **It's even worse:** Our algorithms here look at search trees (game trees), no duplicate pruning.
- ▷ **Example 7.1.10.**
  - ▷ Chess without duplicate pruning:  $35^{100} \approx 10^{154}$ .
  - ▷ Go without duplicate pruning:  $200^{300} \approx 10^{690}$ .

## How To Describe a Game State Space?

- ▷ Like for classical search problems, there are three possible ways to describe a game: blackbox/API description, declarative description, explicit game state space.
- ▷ **Question:** Which ones do humans use?
  - ▷ **Explicit**  $\approx$  Hand over a book with all  $10^{40}$  moves in chess.
  - ▷ **Blackbox**  $\approx$  Give possible chess moves on demand but don't say how they are generated.
- ▷ **Answer:** Declarative!  
With “game description language”  $\hat{=}$  natural language.

## Specialized vs. General Game Playing

- ▷ And which game descriptions do computers use?
  - ▷ **Explicit:** Only in illustrations.
  - ▷ **Blackbox/API:** Assumed description in (This Chapter)
    - ▷ Method of choice for all those game players out there in the market (Chess computers, video game opponents, you name it).
    - ▷ **Programs** designed for, and specialized to, a particular game.
    - ▷ Human knowledge is key: **evaluation functions** (see later), opening databases (chess!!), end game databases.
  - ▷ **Declarative:** **General game playing**, active area of research in AI.
    - ▷ Generic **game description language (GDL)**, based on **logic**.
    - ▷ **Solvers** are given only “the rules of the game”, no other knowledge/input whatsoever (cf. chapter 6).
    - ▷ Regular academic competitions since 2005.

## Our Agenda for This Chapter

- ▷ **Minimax Search:** How to compute an optimal strategy?
  - ▷ **Minimax** is the canonical (and easiest to understand) **algorithm** for *solving* games, i.e., computing an **optimal strategy**.
- ▷ **Evaluation functions:** But what if we don't have the time/memory to solve the entire game?
  - ▷ Given limited time, the best we can do is look ahead as far as we can. **Evaluation functions** tell us how to evaluate the **leaf states** at the cut off.
- ▷ **Alphabeta search:** How to **prune** unnecessary parts of the tree?
  - ▷ Often, we can detect early on that a particular action choice cannot be part of the optimal strategy. We can then stop considering this part of the game tree.
- ▷ **State of the art:** What is the state of affairs, for prominent games, of computer game playing vs. human experts?
  - ▷ Just FYI (not part of the technical content of this course).

## 7.2 Minimax Search

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22061>.

## “Minimax”?

- ▷ We want to compute an **optimal strategy** for player “Max”.
  - ▷ In other words: *We are Max, and our opponent is Min.*
- ▷ **Recall:** We compute the **strategy offline**, before the game begins.
  - During the game, whenever it's our turn, we just look up the corresponding **action**.
- ▷ **Idea:** Use **tree search** using an extension  $\hat{u}$  of the **utility function**  $u$  to **inner nodes**.  $\hat{u}$  is computed **recursively** from  $u$  during search:
  - ▷ **Max** attempts to **maximize**  $\hat{u}(s)$  of the **terminal states** reachable during play.
  - ▷ **Min** attempts to **minimize**  $\hat{u}(s)$ .
- ▷ The computation alternates between **minimization** and **maximization**  $\leadsto$  hence “minimax”.

## Example Tic-Tac-Toe

- ▷ Game tree, current player and **action** marked on the left.
- ▷ Last row: **terminal positions** with their **utility**.

## Minimax: Outline

- ▷ **We max, we min, we max, we min ...**
  1. **Depth first search** in **game tree**, with **Max** in the **root**.
  2. Apply **game utility function** to **terminal positions**.

3. Bottom-up for each inner node  $n$  in the search tree, compute the utility  $\hat{u}(n)$  of  $n$  as follows:
  - ▷ If it's Max's turn: Set  $\hat{u}(n)$  to the maximum of the utilities of  $n$ 's successor nodes.
  - ▷ If it's Min's turn: Set  $\hat{u}(n)$  to the minimum of the utilities of  $n$ 's successor nodes.
4. Selecting a move for Max at the root: Choose one move that leads to a successor node with maximal utility.

## Minimax: Example

- ▷ **Blue numbers:** Utility function  $u$  applied to terminal positions.
- ▷ **Red numbers:** Utilities of inner nodes, as computed by the minimax algorithm.

## The Minimax Algorithm: Pseudo-Code

- ▷ **Definition 7.2.1.** The **minimax algorithm** (often just called **minimax**) is given by the following functions whose input is a state  $s \in S^{\text{Max}}$ , in which Max is to move.

**function** Minimax-Decision( $s$ ) **returns** an action

$v := \text{Max-Value}(s)$

**return** an action yielding value  $v$  in the previous function call

**function** Max-Value( $s$ ) **returns** a utility value

**if** Terminal-Test( $s$ ) **then return**  $u(s)$

$v := -\infty$

**for each**  $a \in \text{Actions}(s)$  **do**

$v := \max(v, \text{Min-Value}(\text{ChildState}(s, a)))$

**return**  $v$

**function** Min-Value( $s$ ) **returns** a utility value

**if** Terminal-Test( $s$ ) **then return**  $u(s)$

$v := +\infty$

**for each**  $a \in \text{Actions}(s)$  **do**

```

 $v := \min(v, \text{Max-Value}(\text{ChildState}(s, a)))$
return v

```

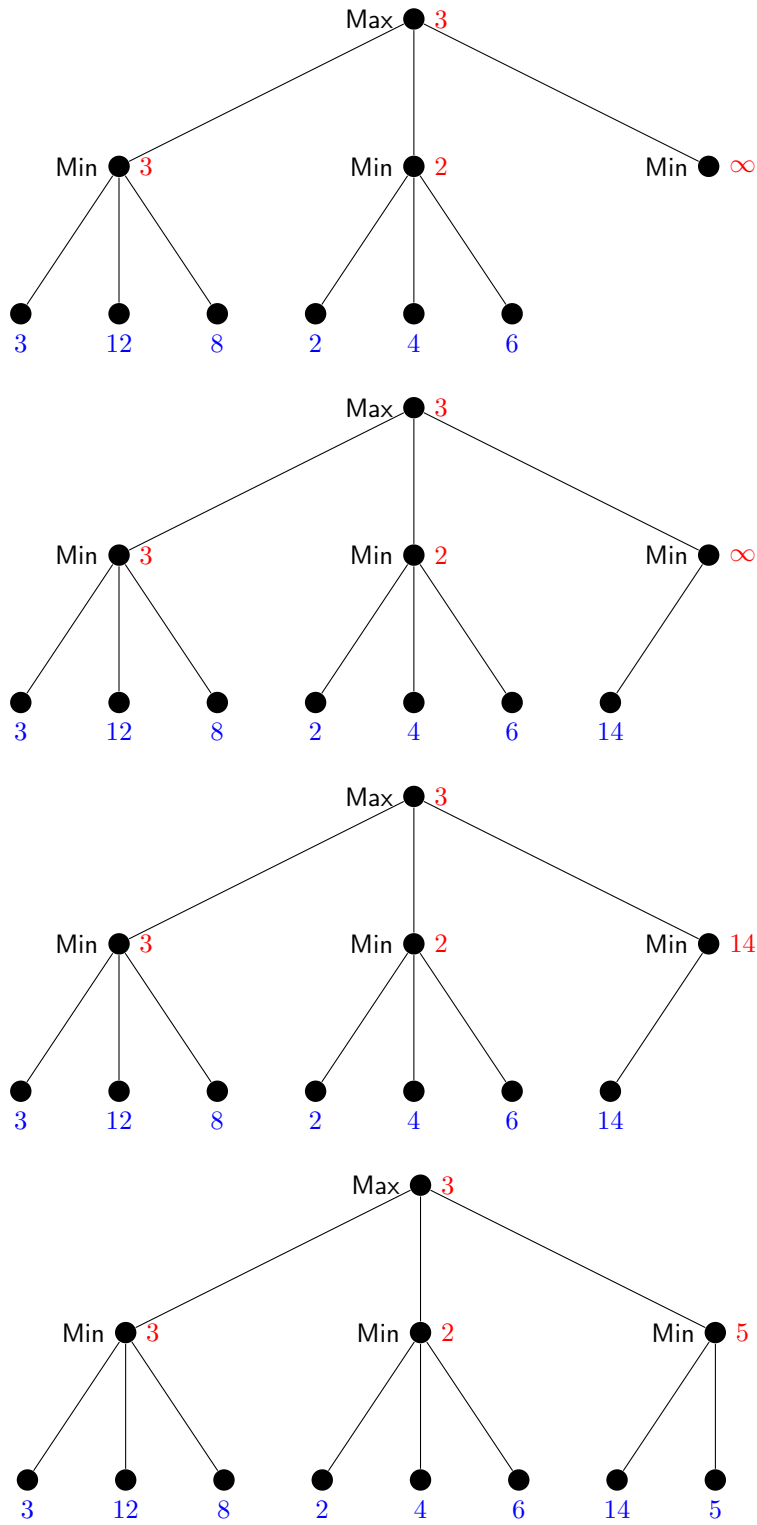

We call **nodes**, where **Max/Min** acts **Max-nodes/Min-nodes**.

## Minimax: Example, Now in Detail

- ▷ So which action for **Max** is returned?
- ▷ Leftmost branch.
- ▷ **Note:** The maximal possible pay-off is higher for the rightmost branch, but assuming perfect play of **Min**, it's better to go left. (Going right would be "relying on your opponent to do something stupid".)

## Minimax, Pro and Contra

- ▷ **Minimax advantages:**
  - ▷ **Minimax** is the simplest possible (reasonable) **search algorithm** for games.

(If any of you sat down, prior to this lecture, to **implement** a Tic-Tac-Toe player, chances are you either looked this up on Wikipedia, or invented it in the process.)

- ▷ Returns an **optimal action**, assuming perfect opponent play.
  - ▷ No matter how the opponent plays, the **utility** of the **terminal state** reached will be at least the value computed for the **root**.
  - ▷ If the opponent plays perfectly, exactly that value will be reached.
- ▷ There's no need to re-run **minimax** for every **game state**: Run it once, **offline** before the game starts. During the actual game, just follow the branches taken in the **tree**. Whenever it's your turn, choose an **action maximizing** the value of the **successor states**.
- ▷ **Minimax disadvantages**: **It's completely infeasible in practice**.
  - ▷ When the **search tree** is too large, we need to limit the search depth and apply an **evaluation function** to the cut off **states**.

## 7.3 Evaluation Functions

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22064>.

We now address the problem that **minimax** is infeasible in practice. As so often, the solution is to eschew **optimal strategies** and to approximate them. In this case, instead of a computed **utility function**, we estimate one that is easy to compute: the **evaluation function**.

### Evaluation Functions for Minimax

- ▷ **Problem**: **Search tree** are too big to search through in **minimax**.
- ▷ **Solution**: We impose a **search depth limit** (also called **horizon**)  $d$ , and apply an **evaluation function** to the **cut-off states**, i.e. **states**  $s$  with  $\text{dp}(s) = d$ .
- ▷ **Definition 7.3.1**. An **evaluation function**  $f$  maps **game states** to numbers:
  - ▷  $f(s)$  is an estimate of the actual value of  $s$  (as would be computed by unlimited-depth **minimax** for  $s$ ).
  - ▷ If **cut-off state** is **terminal**: Just use  $\hat{u}$  instead of  $f$ .
- ▷ Analogy to **heuristic functions** (cf. section 6.5): We want  $f$  to be both (a) accurate and (b) fast.
- ▷ Another analogy: (a) and (b) are in contradiction  $\rightsquigarrow$  need to trade-off accuracy against overhead.
  - ▷ In typical game playing **algorithms** today,  $f$  is inaccurate but very fast. (usually no good methods known for computing accurate  $f$ )

### Example Revisited: Minimax With Depth Limit $d = 2$

- ▷ **Blue numbers:** evaluation function  $f$ , applied to the cut-off states at  $d = 2$ .
- ▷ **Red numbers:** utilities of inner node, as computed by minimax using  $f$ .

## Example Chess

- ▷ Evaluation function in chess:
  - ▷ **Material:** Pawn 1, Knight 3, Bishop 3, Rook 5, Queen 9.
  - ▷ 3 points advantage  $\leadsto$  safe win.
  - ▷ **Mobility:** How many fields do you control?
  - ▷ King safety, Pawn structure, ...
- ▷ Note how simple this is! (probably is not how Kasparov evaluates his positions)

## Linear Evaluation Functions

- ▷ **Problem:** How to come up with evaluation functions?
- ▷ **Definition 7.3.2.** A common approach is to use a **weighted linear function** for  $f$ , i.e. given a **sequence of features**  $f_i: S \rightarrow \mathbb{R}$  and a corresponding **sequence of weights**  $w_i \in \mathbb{R}$ ,  $f$  is of the form  $f(s) := w_1 \cdot f_1(s) + w_2 \cdot f_2(s) + \dots + w_n \cdot f_n(s)$
- ▷ **Problem:** How to obtain these **weighted linear functions**?
  - ▷ **Weights**  $w_i$  can be learned automatically. (learning agent)
  - ▷ The **features**  $f_i$ , however, have to be designed by human experts.
- ▷ **Note:** Very fast, very simplistic.
- ▷ **Observation:** Can be computed **incrementally**: In transition  $s \xrightarrow{a} s'$ , adapt  $f(s)$  to  $f(s')$  by considering only those **features** whose **values** have changed.

This assumes that the **features** (their contribution towards the actual value of the state) are independent. That's usually not the case (e.g. the **value** of a rook depends on the pawn structure).

### The Horizon Problem

- ▷ **Problem:** Critical aspects of the game can be cut off by the **horizon**.

Black to move

- ▷ Who's gonna win here?
  - ▷ White wins (pawn cannot be prevented from becoming a queen.)
  - ▷ Black has a +4 advantage in material, so if we cut-off here then our **evaluation function** will say "100, black wins".
  - ▷ The loss for black is "beyond our horizon" unless we search extremely deeply: black can hold off the end by repeatedly giving check to white's king.

### So, How Deeply to Search?

- ▷ **Goal:** In given time, search as deeply as possible.
- ▷ **Problem:** Very difficult to predict search **running time**. (need an anytime algorithm)
- ▷ **Solution:** Iterative deepening search.
  - ▷ Search with **depth limit**  $d = 1, 2, 3, \dots$
  - ▷ When time is up: return result of deepest completed search.
- ▷ **Definition 7.3.3 (Better Solution).** The **quiescent search algorithm** uses a dynamically adapted search depth  $d$ : It searches more deeply in **unquiet** positions, where value of **evaluation function** changes a lot in neighboring **states**.
- ▷ **Example 7.3.4.** In **quiescent search** for **chess**:
  - ▷ piece exchange situations ("you take mine, I take yours") are very **unquiet**
  - ▷  $\rightsquigarrow$  Keep searching until the end of the piece exchange is reached.

## 7.4 Alpha-Beta Search

We have seen that **evaluation functions** can overcome the **combinatorial explosion** induced by

minimax search. But we can do even better: certain parts of the minimax search tree can be safely ignored, since we can prove that they will only sub-optimal results. We discuss the technique of alpha-beta-pruning in detail as an example of such pruning methods in search algorithms.

### When We Already Know We Can Do Better Than This

- ▷ Say  $n > m$ .
- ▷ By choosing to go to the left in search node (A), Max already can get utility of at least  $n$  in this part of the game.
- ▷ So, if “later on” (further down in the same subtree), in search node (B) we already know that Min can force Max to get value  $m < n$ .
- ▷ Then Max will play differently in (A) so we will never actually get to (B).

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 218 2024-02-08

### Alpha Pruning: Basic Idea

▷ **Question:** Can we save some work here?

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 219 2024-02-08

### Alpha Pruning: Basic Idea (Continued)

▷ **Answer:** Yes! We already know at this point that the middle action won't be taken by **Max**.

▷ **Idea:** We can use this to **prune** the **search tree**  $\leadsto$  **better algorithm**

## Alpha Pruning

▷ **Definition 7.4.1.** For each **node**  $n$  in a **minimax search tree**, the **alpha value**  $\alpha(n)$  is the highest **Max-node utility** that search has encountered on its **path** from the **root** to  $n$ .

▷ **Example 7.4.2 (Computing alpha values).**

▷ **How to use  $\alpha$ ?** In a Min-node  $n$ , if  $\hat{u}(n') \leq \alpha(n)$  for one of the successors, then stop considering  $n$ . (pruning out its remaining successors)

## Alpha-Beta Pruning

### ▷ Recall:

- ▷ **What is  $\alpha$ :** For each search node  $n$ , the highest Max-node utility that search has encountered on its path from the root to  $n$ .
- ▷ **How to use  $\alpha$ :** In a Min-node  $n$ , if one of the successors already has utility  $\leq \alpha(n)$ , then stop considering  $n$ . (Pruning out its remaining successors)
- ▷ **Idea:** We can use a dual method for Min!
- ▷ **Definition 7.4.3.** For each node  $n$  in a minimax search tree, the beta value  $\beta(n)$  is the highest Min-node utility that search has encountered on its path from the root to  $n$ .
- ▷ **How to use  $\beta$ :** In a Max-node  $n$ , if one of the successors already has utility  $\geq \beta(n)$ , then stop considering  $n$ . (pruning out its remaining successors)
- ▷ ... and of course we can use  $\alpha$  and  $\beta$  together!  $\leadsto$  alphabeta-pruning

## Alpha-Beta Search: Pseudocode

- ▷ **Definition 7.4.4.** The alphabeta search algorithm is given by the following pseudocode

**function** Alpha-Beta-Search ( $s$ ) **returns** an action

$v := \text{Max-Value}(s, -\infty, +\infty)$

**return** an action yielding value  $v$  in the previous function call

**function** Max-Value( $s, \alpha, \beta$ ) **returns** a utility value

**if** Terminal-Test( $s$ ) **then return**  $u(s)$

$v := -\infty$

**for each**  $a \in \text{Actions}(s)$  **do**

$v := \max(v, \text{Min-Value}(\text{ChildState}(s, a), \alpha, \beta))$

$\alpha := \max(\alpha, v)$

**if**  $v \geq \beta$  **then return**  $v$  /\* Here:  $v \geq \beta \Leftrightarrow \alpha \geq \beta$  \*/

**return**  $v$

**function** Min-Value( $s, \alpha, \beta$ ) **returns** a utility value

**if** Terminal-Test( $s$ ) **then return**  $u(s)$

$v := +\infty$

**for each**  $a \in \text{Actions}(s)$  **do**

$v := \min(v, \text{Max-Value}(\text{ChildState}(s, a), \alpha, \beta))$

$\beta := \min(\beta, v)$

**if**  $v \leq \alpha$  **then return**  $v$  /\* Here:  $v \leq \alpha \Leftrightarrow \alpha \geq \beta$  \*/

**return**  $v$

$\hat{=}$  Minimax (slide 209) +  $\alpha/\beta$  book-keeping and pruning.

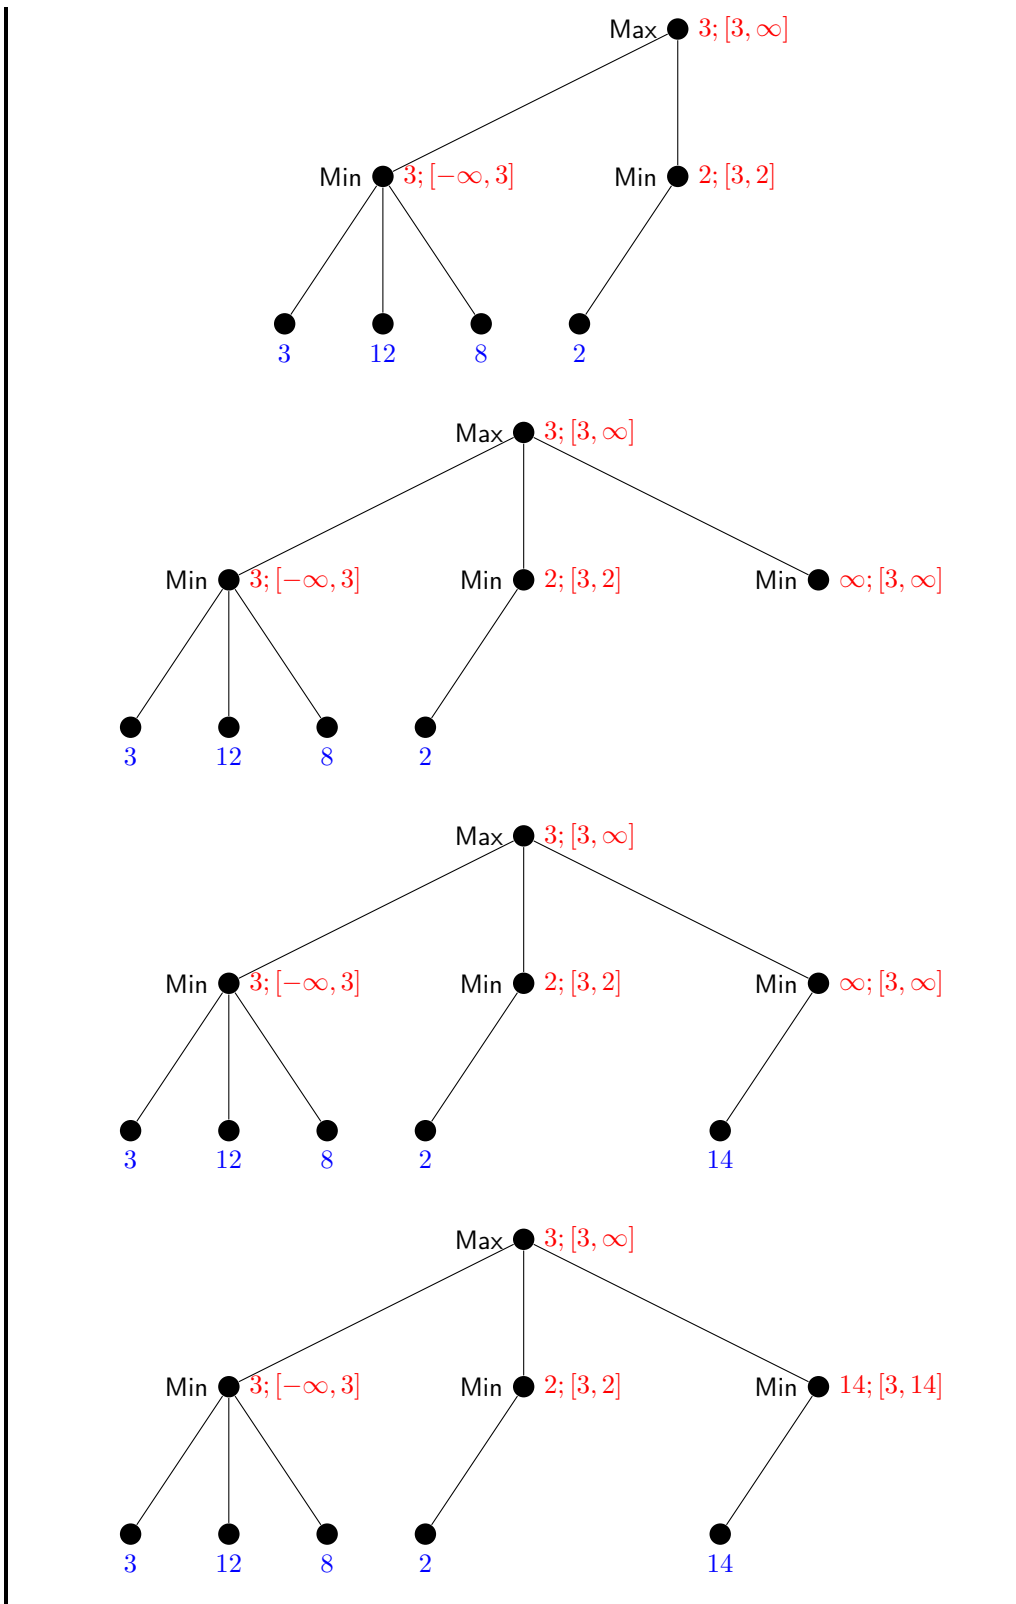

**Note:** Note that  $\alpha$  only gets assigned a value in Max-nodes, and  $\beta$  only gets assigned a value in Min-nodes.

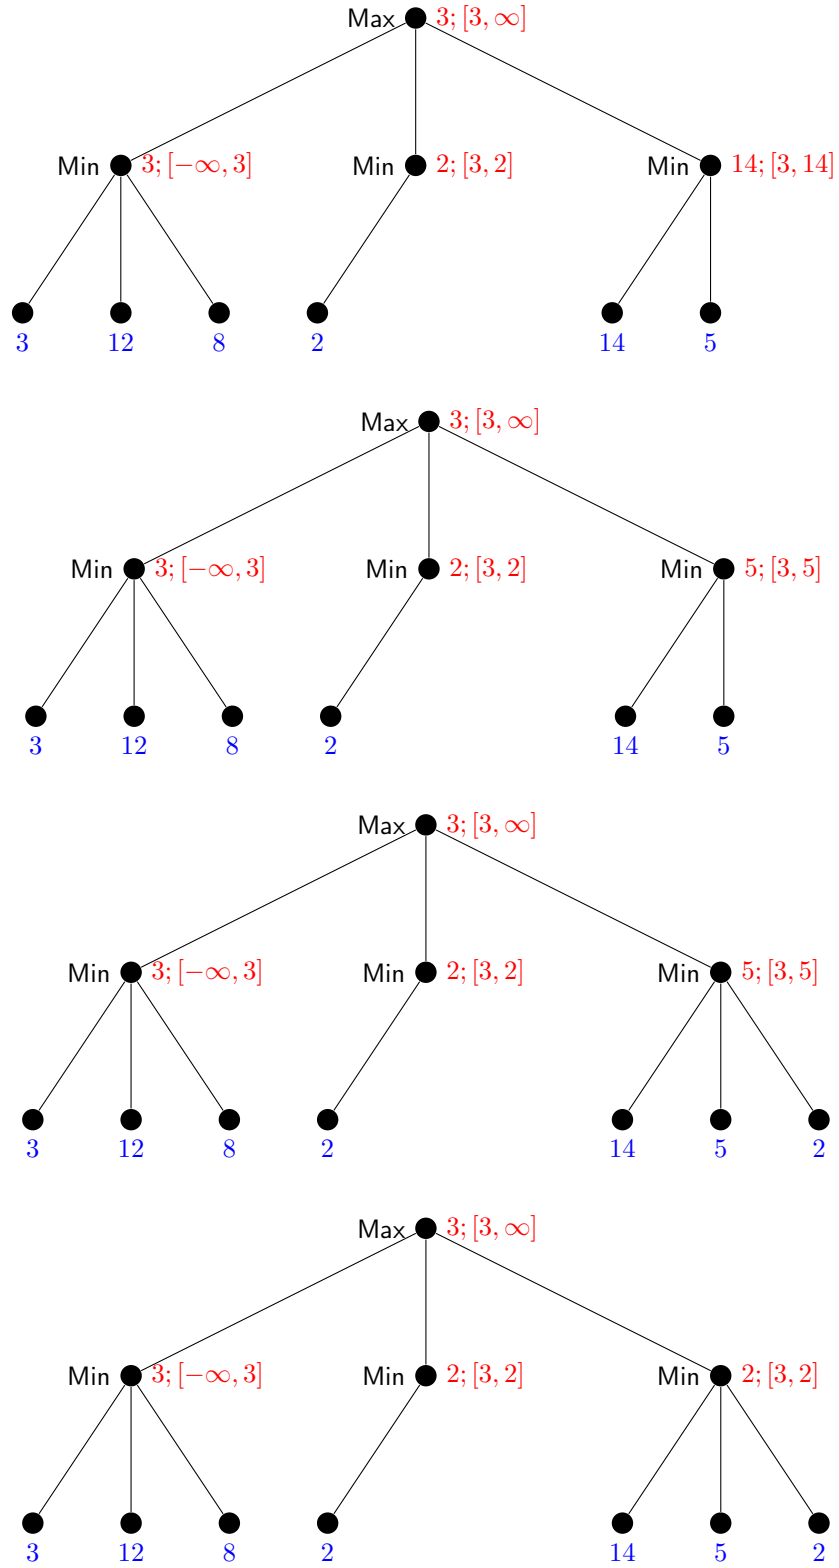

## Alpha-Beta Search: Example

▷ **Notation:**  $v; [\alpha, \beta]$

▷ **Note:** We could have saved work by choosing the opposite order for the successors

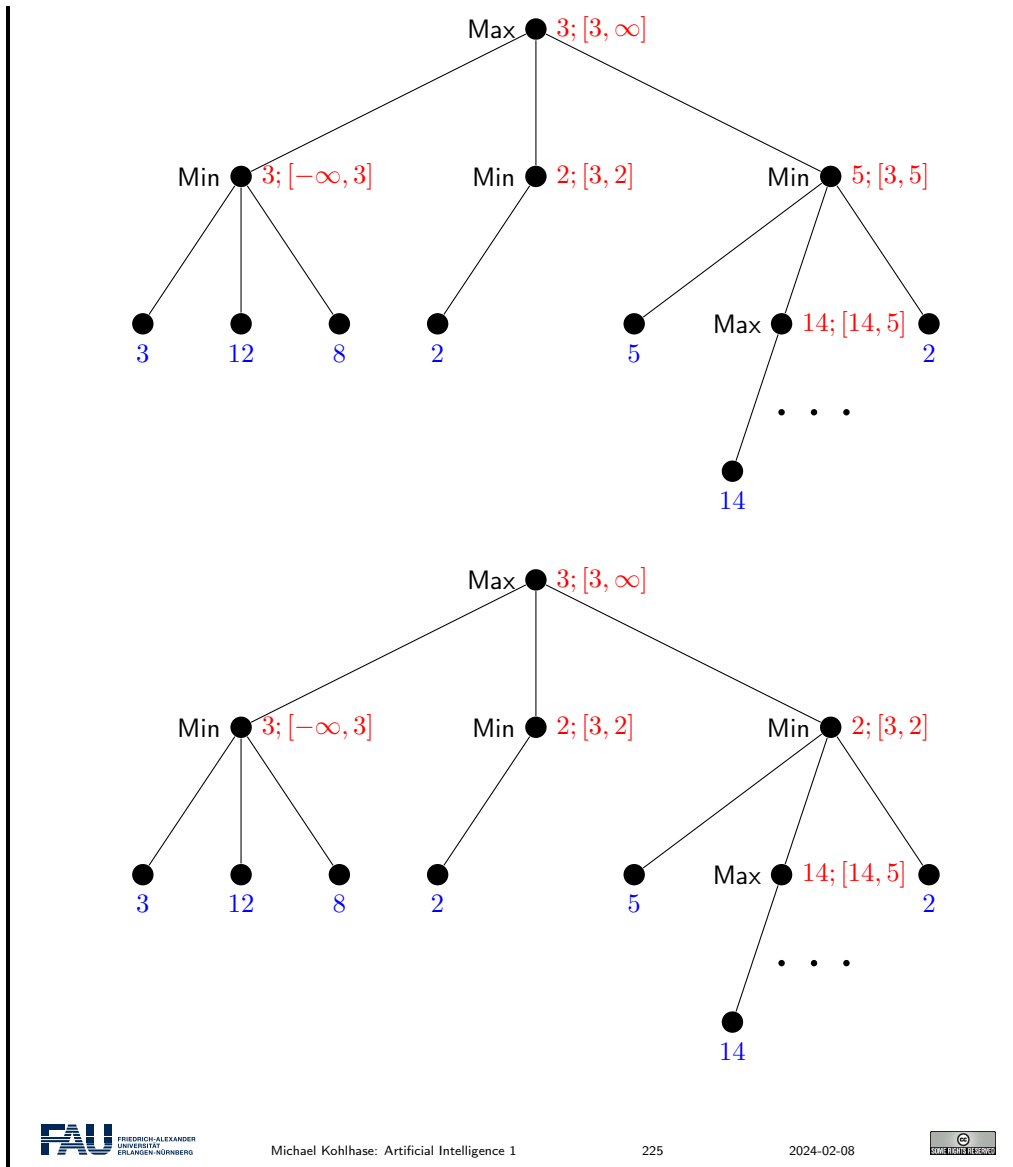

of the rightmost **Min-node**.  
 Choosing the best moves (for each of **Max** and **Min**) first yields more **pruning**!

### Alpha-Beta Search: Modified Example

▷ Showing off some actual  $\beta$  pruning:

## How Much Pruning Do We Get?

- ▷ Choosing the best moves first yields most pruning in alphabeta search.
  - ▷ The maximizing moves for Max, the minimizing moves for Min.
- ▷ **Observation:** Assuming game tree with branching factor  $b$  and depth limit  $d$ :
  - ▷ Minimax would have to search  $b^d$  nodes.
  - ▷ **Best case:** If we always choose the best moves first, then the search tree is reduced to  $b^{\frac{d}{2}}$  nodes!
  - ▷ **Practice:** It is often possible to get very close to the best case by simple move-ordering methods.
- ▷ **Example 7.4.5 (Chess).**

- ▷ Move ordering: Try captures first, then threats, then forward moves, then backward moves.
- ▷ From  $35^d$  to  $35^{\frac{d}{2}}$ . E.g., if we have the time to search a billion ( $10^9$ ) nodes, then **minimax** looks ahead  $d = 6$  moves, i.e., 3 rounds (white-black) of the game. Alpha-beta search looks ahead 6 rounds.

## 7.5 Monte-Carlo Tree Search (MCTS)

**Video Nuggets** covering this section can be found at <https://fau.tv/clip/id/22259> and <https://fau.tv/clip/id/22262>.

We will now come to the most visible game-play program in recent times: The **AlphaGo** system for the game of **go**. This has been out of reach of the **state of the art** (and thus for **alphabeta search**) until 2016. This challenge was cracked by a different technique, which we will discuss in this section.

And now ...

- ▷ **AlphaGo = Monte Carlo tree search (AI-1) + neural networks (AI-2)**

CC-BY-SA: Buster Benson@ <https://www.flickr.com/photos/erikbenson/25717574115>

### Monte-Carlo Tree Search: Basic Ideas

- ▷ **Observation:** We do not always have good **evaluation functions**.
- ▷ **Definition 7.5.1.** For **Monte Carlo sampling** we evaluate actions through **sampling**.
  - ▷ When deciding which **action** to take on **game state**  $s$ :
 

```

while time not up do
 select action a applicable to s
 run a random sample from a until terminal state t
return an a for s with maximal average $u(t)$

```
- ▷ **Definition 7.5.2.** For the **Monte Carlo tree search algorithm (MCTS)** we maintain a **search tree**  $T$ , the **MCTS tree**.

```

while time not up do
 apply actions within T to select a leaf state s'
 select action a' applicable to s' , run random sample from a'
 add s' to T , update averages etc.
return an a for s with maximal average $u(t)$
When executing a , keep the part of T below a .

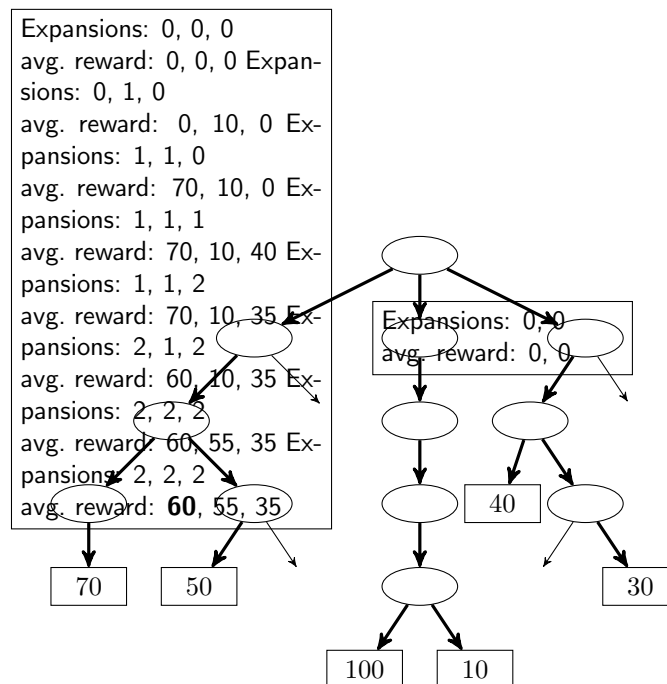

```

- ▷ Compared to **alphabeta search**: no exhaustive **enumeration**.
- ▷ **Pro**: **running time & memory**.
- ▷ **Contra**: need good guidance how to select and **sample**.

This looks only at a fraction of the search tree, so it is crucial to have good guidance *where to go*, i.e. which part of the search tree to look at.

### Monte-Carlo Sampling: Illustration of Sampling

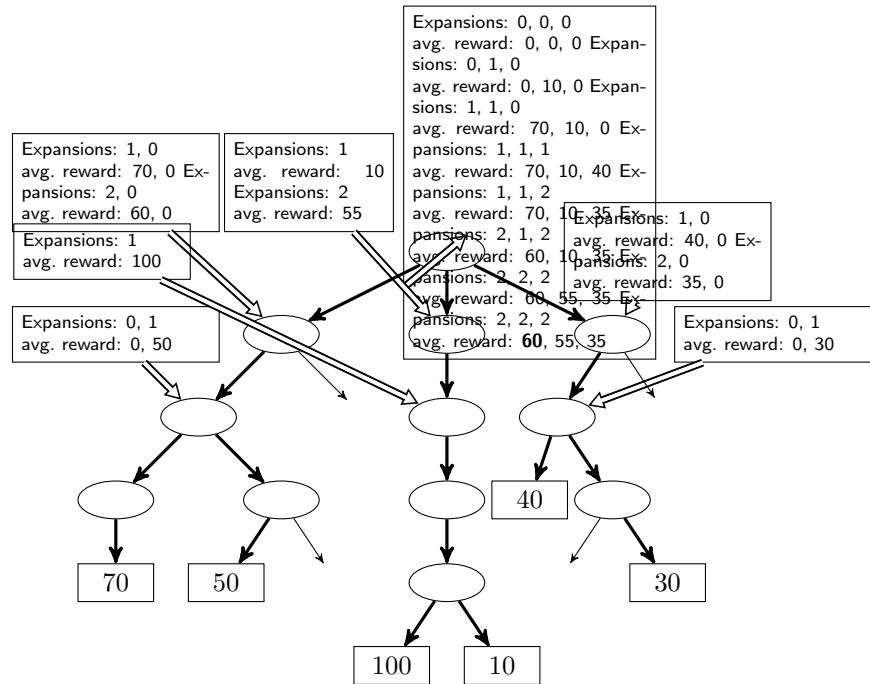

- ▷ **Idea**: Sample the search tree keeping track of the average utilities.
- ▷ **Example 7.5.3 (Single-player, for simplicity)**. (with adversary, distinguish max/min nodes)

The **sampling** goes middle, left, right, right, left, middle. Then it stops and selects the highest-average action, 60, left. After first **sample**, when values in initial state are being updated, we have the following “expansions” and “avg. reward fields”: small number of expansions favored for exploration: visit parts of the tree rarely visited before, what is out there? avg. reward: high values favored for exploitation: focus on promising parts of the search tree.

## Monte-Carlo Tree Search: Building the Tree

- ▷ **Idea:** We can save work by building the **tree** as we go along.
- ▷ **Example 7.5.4 (Redoing the previous example).**

This is the exact same search as on previous slide, but **incrementally** building the search tree, by always keeping the first state of the **sample**. The first three iterations middle, left, right, go to show the tree extension; do point out here that, like the root node, the nodes added to the tree have expansions and avg reward counters for every applicable action. Then in next iteration right, after 30 leaf node was found, an important thing is that the averages get updated *\*along the entire path\**, i.e., not only in the root as we did before, but also in the nodes along the way. After all six iterations have been done, as before we select the action left, value 60; but we keep the part of the tree below that action, “saving relevant work already done before”.

## How to Guide the Search in MCTS?

- ▷ **How to sample?:** What exactly is “random”?
- ▷ **Classical formulation:** balance exploitation vs. exploration.
  - ▷ **Exploitation:** Prefer moves that have high average already (**interesting regions of state space**)
  - ▷ **Exploration:** Prefer moves that have not been tried a lot yet (**don't overlook other, possibly better, options**)
- ▷ **UCT:** “Upper Confidence bounds applied to Trees” [KS06].

- ▷ Inspired by Multi-Armed Bandit (as in: Casino) problems.
- ▷ Basically a formula defining the balance. Very popular (buzzword).
- ▷ Recent critics (e.g. [FD14]): **Exploitation** in search is very different from the Casino, as the “accumulated rewards” are fictitious (we’re only thinking about the game, not actually playing and winning/losing all the time).

## AlphaGo: Overview

- ▷ **Definition 7.5.5 (Neural Networks in AlphaGo).**
  - ▷ **Policy networks:** Given a state  $s$ , output a probability distribution over the actions applicable in  $s$ .
  - ▷ **Value networks:** Given a state  $s$ , output a number estimating the game value of  $s$ .
- ▷ **Combination with MCTS:**
  - ▷ Policy networks bias the action choices within the **MCTS tree** (and hence the **leaf state** selection), and bias the random **samples**.
  - ▷ Value networks are an additional source of state values in the **MCTS tree**, along with the random **samples**.
- ▷ And now in a little more detail

## Neural Networks in AlphaGo

- ▷ **Neural network training pipeline and architecture:**

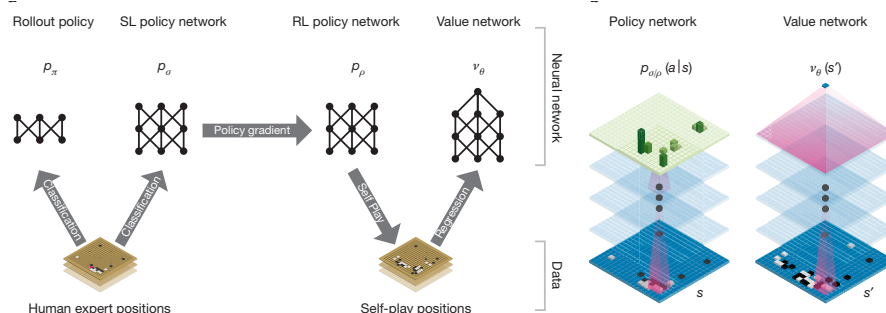

Illustration taken from [Sil+16] .

- ▷ **Rollout policy**  $p_\pi$ : Simple but fast,  $\approx$  prior work on Go.
- ▷ **SL policy network**  $p_\sigma$ : Supervised learning, human-expert data (“learn to choose an expert action”).
- ▷ **RL policy network**  $p_\rho$ : Reinforcement learning, self-play (“learn to win”).

- ▷ **Value network**  $v_\theta$ : Use self-play games with  $p_\rho$  as training data for game-position evaluation  $v_\theta$  (“predict which player will win in this state”).

### Comments on the Figure:

- A fast rollout policy  $p_\pi$  and supervised learning (SL) policy network  $p_\sigma$  are trained to predict human expert moves in a data set of positions. A reinforcement learning (RL) policy network  $p_\rho$  is initialized to the SL policy network, and is then improved by policy gradient learning to **maximize** the outcome (that is, winning more games) against previous versions of the policy network. A new data set is generated by playing games of self-play with the RL policy network. Finally, a value network  $v_\theta$  is trained by regression to predict the **expected** outcome (that is, whether the current player wins) in positions from the self-play data set.
- Schematic representation of the neural network architecture used in **AlphaGo**. The **policy network** takes a representation of the board position  $s$  as its input, passes it through many convolutional layers with parameters  $\sigma$  (SL policy network) or  $\rho$  (RL policy network), and outputs a probability distribution  $p_\sigma(a|s)$  or  $p_\rho(a|s)$  over legal moves  $a$ , represented by a probability map over the board. The value network similarly uses many convolutional layers with parameters  $\theta$ , but outputs a scalar value  $v_\theta(s')$  that predicts the **expected** outcome in position  $s'$ .

### Neural Networks + MCTS in AlphaGo

#### ▷ Monte Carlo tree search in AlphaGo:

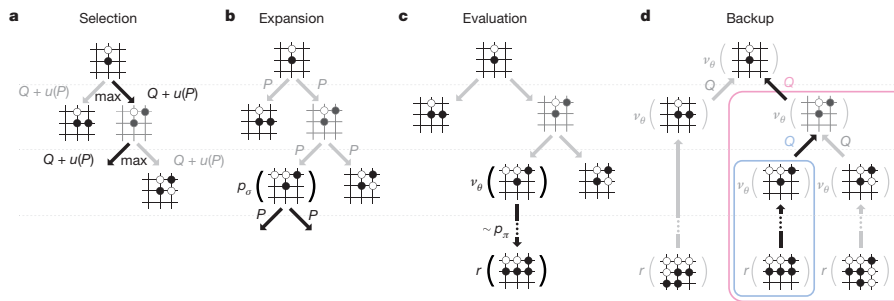

Illustration taken from [Sil+16]

- ▷ **Rollout policy**  $p_\pi$ : Action choice in random **samples**.
- ▷ **SL policy network**  $p_\sigma$ : Action choice bias within the UCTS tree (stored as “ $P$ ”, gets smaller to “ $u(P)$ ” with number of visits); along with quality  $Q$ .
- ▷ **RL policy network**  $p_\rho$ : Not used here (used only to learn  $v_\theta$ ).
- ▷ **Value network**  $v_\theta$ : Used to evaluate **leaf states**  $s$ , in linear sum with the value returned by a random **sample** on  $s$ .

### Comments on the Figure:

- Each simulation traverses the tree by selecting the edge with maximum action value  $Q$ , plus a bonus  $u(P)$  that depends on a stored prior probability  $P$  for that edge.

- b The **leaf node** may be expanded; the new **node** is processed once by the policy network  $p_\sigma$  and the output probabilities are stored as prior probabilities  $P$  for each action.
- c At the end of a simulation, the **leaf node** is evaluated in two ways:
- using the value network  $v_\theta$ ,
  - and by running a rollout to the end of the game
- with the fast rollout policy  $p_\pi$ , then computing the winner with function  $r$ .
- d Action values  $Q$  are updated to track the mean value of all evaluations  $r(\cdot)$  and  $v_\theta(\cdot)$  in the subtree below that action.

**AlphaGo, Conclusion?:** This is definitely a great achievement!

- “Search + neural networks” looks like a great formula for general problem solving.
- expect to see lots of research on this in the coming decade(s).
- The AlphaGo design is quite intricate (architecture, learning workflow, training data design, neural network architectures, ...).
- How much of this is reusable in/generalizes to other problems?
- Still lots of human expertise in here. Not as much, like in **chess**, about the game itself. But rather, in the design of the neural networks + learning architecture.

## 7.6 State of the Art

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22250>.

### State of the Art

---

▷ **Some well-known board games:**

- ▷ **Chess:** Up next.
- ▷ **Othello (Reversi):** In 1997, “Logistello” beat the human world champion. Best **computer** players now are clearly better than best human players.
- ▷ **Checkers (Dame):** Since 1994, “Chinook” is the official world champion. In 2007, it was shown to be *unbeatable*: Checkers is *solved*. (We know the exact value of, and optimal strategy for, the initial state.)
- ▷ **Go:** In 2016, **AlphaGo** beat the Grandmaster Lee Sedol, cracking the “holy grail” of board games. In 2017, “AlphaZero” – a variant of **AlphaGo** with zero prior knowledge beat all reigning champion systems in all board games (including **AlphaGo**) 100/0 after 24h of self-play.
- ▷ **Intuition:** Board Games are considered a “solved problem” from the **AI** perspective.

Computer Chess: “Deep Blue” beat Garry Kasparov in 1997

Duell Kasparow gegen Deep Blue (1997): Demütigende Niederlage

- ▷ 6 games, final score 3.5 : 2.5.
- ▷ Specialized **chess** hardware, 30 nodes with 16 processors each.
- ▷ **Alphabeta** search plus human knowledge. (more details in a moment)
- ▷ Nowadays, standard PC hardware plays at world champion level.

## Computer Chess: Famous Quotes

- ▷ The **chess** machine is an ideal one to start with, since (Claude Shannon (1949))
  1. the problem is sharply defined both in allowed operations (the moves) and in the ultimate goal (checkmate),
  2. it is neither so simple as to be trivial nor too difficult for satisfactory solution,
  3. chess is generally considered to require “thinking” for skilful play, [...]
  4. the discrete structure of chess fits well into the digital nature of modern **computers**.
- ▷ Chess is the drosophila of **Artificial Intelligence**. (Alexander Kronrod (1965))

## Computer Chess: Another Famous Quote

- ▷ In 1965, the Russian **mathematician** Alexander Kronrod said, “**Chess** is the Drosophila of artificial intelligence.”
- However, computer **chess** has developed much as genetics might have if the geneticists had concentrated their efforts starting in 1910 on breeding racing Drosophilae. We would have some science, but mainly we would have very fast fruit flies. (John McCarthy (1997))

## 7.7 Conclusion

### Summary

- ▷ Games (2-player turn-taking zero-sum discrete and finite games) can be understood as a simple extension of classical **search problems**.
- ▷ Each player tries to reach a terminal state with the best possible **utility** (maximal vs. minimal).

- ▷ **Minimax** searches the game depth-first, max'ing and min'ing at the respective turns of each player. It yields perfect play, but takes time  $\mathcal{O}(b^d)$  where  $b$  is the branching factor and  $d$  the search depth.
- ▷ Except in trivial games (Tic-Tac-Toe), **minimax** needs a depth limit and apply an **evaluation function** to estimate the value of the cut-off states.
- ▷ Alpha-beta search remembers the best values achieved for each player elsewhere in the tree already, and **prunes** out sub-trees that won't be reached in the game.
- ▷ **Monte Carlo tree search (MCTS)** **samples** game branches, and averages the findings. **AlphaGo** controls this using **neural networks: evaluation function** ("value network"), and action filter ("policy network").

### Suggested Reading:

- *Chapter 5: Adversarial Search*, Sections 5.1 – 5.4 [RN09].
  - Section 5.1 corresponds to my “Introduction”, Section 5.2 corresponds to my “Minimax Search”, Section 5.3 corresponds to my “Alpha-Beta Search”. I have tried to add some additional clarifying illustrations. RN gives many complementary explanations, nice as additional background reading.
  - Section 5.4 corresponds to my “Evaluation Functions”, but discusses additional aspects relating to narrowing the search and look-up from opening/termination databases. Nice as additional background reading.
  - I suppose a discussion of MCTS and AlphaGo will be added to the next edition . . .

## Chapter 8

# Constraint Satisfaction Problems

In the last chapters we have studied methods for “general problem”, i.e. such that are applicable to all problems that are expressible in terms of *states* and “actions”. It is crucial to realize that these states were *atomic*, which makes the *algorithms* employed (search *algorithms*) relatively simple and generic, but does not let them exploit the any knowledge we might have about the *internal structure of states*.

In this chapter, we will look into *algorithms* that do just that by progressing to *factored states* representations. We will see that this allows for *algorithms* that are many orders of magnitude more *efficient* than search *algorithms*.

To give an intuition for *factored states* representations we, we present some motivational examples in section 8.1 and go into detail of the Waltz *algorithm*, which gave rise to the main ideas of constraint satisfaction *algorithms* in section 8.2. section 8.3 and section 8.5 define constraint satisfaction problems formally and use that to develop a class of *backtracking/search* based *algorithms*. The main contribution of the *factored states* representations is that we can formulate advanced search *heuristics* that guide search based on the structure of the states.

### 8.1 Constraint Satisfaction Problems: Motivation

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22251>.

#### A (Constraint Satisfaction) Problem

## Constraint Satisfaction Problems (CSPs)

- ▷ Standard search problem: state is a “black box” any old data structure that supports goal test, eval, successor state, ...
- ▷ **Definition 8.1.2.** A **constraint satisfaction problem (CSP)** is a search problem, where the states are given by a finite set  $V := \{X_1, \dots, X_n\}$  of variables and domains  $\{D_v | v \in V\}$  and the goal state are specified by a set of constraints specifying allowable combinations of values for subsets of variables.
- ▷ **Definition 8.1.3.** A constraint network  $\gamma$  is **satisfiable**, iff it has a **solution**: a total, consistent variable assignment  $\varphi$ . We say that  $\varphi$  **solves**  $\gamma$ .
- ▷ **Definition 8.1.4.** The process of finding solutions to CSPs is called **constraint solving**.
- ▷ **Remark 8.1.5.** We are using **factored** representation for world states now.
- ▷ Simple example of a *formal representation language*
- ▷ Allows useful *general-purpose algorithms* with more power than standard *tree search algorithm*.

## Another Constraint Satisfaction Problem

- ▷ **Example 8.1.6 (SuDoKu).** Fill the cells with row/column/block-unique digits

|   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|
| 2 | 5 |   |   | 3 |   | 9 |   | 1 |
|   | 1 |   |   |   | 4 |   |   |   |
| 4 |   | 7 |   |   |   | 2 |   | 8 |
|   |   | 5 | 2 |   |   |   |   |   |
|   |   |   |   | 9 | 8 | 1 |   |   |
| 4 |   |   |   | 3 |   |   |   |   |
|   |   |   | 3 | 6 |   |   | 7 | 2 |
|   | 7 |   |   |   |   |   |   | 3 |
| 9 | 3 |   |   |   | 6 |   |   | 4 |

~

|   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|
| 2 | 5 | 8 | 7 | 3 | 6 | 9 | 4 | 1 |
| 6 | 1 | 9 | 8 | 2 | 4 | 3 | 5 | 7 |
| 4 | 3 | 7 | 9 | 1 | 5 | 2 | 6 | 8 |
| 3 | 9 | 5 | 2 | 7 | 1 | 4 | 8 | 6 |
| 7 | 6 | 2 | 4 | 9 | 8 | 1 | 3 | 5 |
| 8 | 4 | 1 | 6 | 5 | 3 | 7 | 2 | 9 |
| 1 | 8 | 4 | 3 | 6 | 9 | 5 | 7 | 2 |
| 5 | 7 | 6 | 1 | 4 | 2 | 8 | 9 | 3 |
| 9 | 2 | 3 | 5 | 8 | 7 | 6 | 1 | 4 |

- ▷ **Variables:** The 81 cells.
- ▷ **Domains:** Numbers 1, ..., 9.
- ▷ **Constraints:** Each number only once in each row, column, block.

## CSP Example: Map-Coloring

▷ **Definition 8.1.7.** Given a map  $M$ , the **map coloring** problem is to assign colors to regions in a map so that no adjoining regions have the same color.

▷ **Example 8.1.8 (Map coloring in Australia).**

- ▷ **Variables:** WA, NT, Q, NSW, V, SA, T
- ▷ **Domains:**  $D_i = \{\text{red, green, blue}\}$
- ▷ **Constraints:** adjacent regions must have different colors e.g.,  $WA \neq NT$  (if the language allows this), or  $\langle WA, NT \rangle \in \{\langle \text{red, green} \rangle, \langle \text{red, blue} \rangle, \langle \text{green, red} \rangle, \dots\}$

- ▷ **Intuition:** solutions map variables to domain values satisfying all constraints,
- ▷ e.g.,  $\{WA = \text{red}, NT = \text{green}, \dots\}$

## Bundesliga Constraints

- ▷ **Variables:**  $v_{A \text{ vs. } B}$  where  $A$  and  $B$  are teams, with **domains**  $\{1, \dots, 34\}$ : For each match, the index of the weekend where it is scheduled.
- ▷ (Some) **constraints:**

**1. Bundesliga**  
DFB-Pokal, Champions-League, Europa-League, Länderspiele

- ▷ If  $\{A, B\} \cap \{C, D\} \neq \emptyset$ :  $v_{Avs.B} \neq v_{Cvs.D}$  (each team only one match per day).
- ▷ If  $\{A, B\} = \{C, D\}$ :  $v_{Avs.B} \leq 17 < v_{Cvs.D}$  or  $v_{Cvs.D} \leq 17 < v_{Avs.B}$  (each pairing exactly once in each half-season).
- ▷ If  $A = C$ :  $v_{Avs.B} + 1 \neq v_{Cvs.D}$  (each team alternates between home matches and away matches).
- ▷ Leading teams of last season meet near the end of each half-season.
- ▷ ...

## How to Solve the Bundesliga Constraints?

- ▷ 306 nested for-loops (for each of the 306 matches), each ranging from 1 to 306. Within the innermost loop, test whether the current values are (a) a permutation and, if so, (b) a legal Bundesliga schedule.
  - ▷ **Estimated running time:** End of this universe, and the next couple billion ones after it ...
- ▷ Directly enumerate all **permutations** of the numbers  $1, \dots, 306$ , test for each whether it's a legal Bundesliga schedule.
  - ▷ **Estimated running time:** Maybe only the time span of a few thousand universes.
- ▷ View this as **variables/constraints** and use **backtracking** (this chapter)
  - ▷ **Executed running time:** About 1 minute.
- ▷ **How do they actually do it?:** Modern **computers** and **CSP** methods: fractions of a second. 19th (20th/21st?) century: Combinatorics and manual work.
- ▷ **Try it yourself:** with an off-the shelf **CSP** solver, e.g. Minion [Min]

## More Constraint Satisfaction Problems

### Traveling Tournament Problem

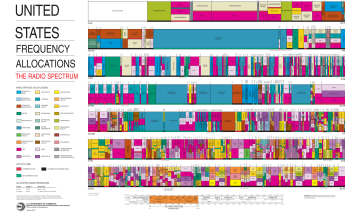

### Scheduling

### Timetabling

### Radio Frequency Assignment

FRIEDRICH-ALEXANDER

2024-02-08

1. U.S. Major League Baseball, 30 teams, each 162 games. There's one crucial additional difficulty, in comparison to Bundesliga. Which one? Travel is a major issue here!! Hence "Traveling Tournament Problem" in reference to the TSP.
2. This particular scheduling problem is called "car sequencing", how to most **efficiently** get cars through the available machines when making the final customer configuration (non-standard/flexible/custom extras).
3. Another common form of scheduling ...
4. The problem of assigning radio frequencies so that all can operate together without noticeable interference. **Variable domains** are available frequencies, **constraints** take form of  $|x - y| > \delta_{xy}$ , where delta depends on the position of  $x$  and  $y$  as well as the physical environment.

## Our Agenda for This Topic

- ▷ Our treatment of the topic "Constraint Satisfaction Problems" consists of Chapters 7 and 8. in [RN03]
- ▷ **This Chapter:** Basic definitions and concepts; naïve **backtracking search**.
  - ▷ Sets up the framework. **Backtracking** underlies many successful **algorithms** for solving **constraint satisfaction problems** (and, naturally, we start with the simplest version thereof).
- ▷ **Next Chapter:** **Constraint propagation** and **decomposition** methods.
  - ▷ **Constraint propagation** reduces the **search space** of **backtracking**. **Decomposition** methods break the problem into smaller pieces. Both are crucial for **efficiency** in practice.

## Our Agenda for This Chapter

- ▷ How are **constraint networks**, and **assignments**, **consistency**, **solutions**: How are **constraint satisfaction problems** defined? What is a **solution**?
  - ▷ Get ourselves on firm ground.
- ▷ **Naïve Backtracking**: How does backtracking work? What are its main weaknesses?
  - ▷ Serves to understand the basic workings of this wide-spread **algorithm**, and to motivate its enhancements.
- ▷ **Variable- and Value Ordering**: How should we guide **backtracking searches**?
  - ▷ Simple methods for making **backtracking** aware of the structure of the problem, and thereby reduce search.

## 8.2 The Waltz Algorithm

We will now have a detailed look at the problem (and innovative solution) that started the field of **constraint satisfaction problems**.

### Background:

Adolfo Guzman worked on an **algorithm** to count the number of simple objects (like children's blocks) in a line drawing. David Huffman formalized the problem and limited it to objects in general position, such that the vertices are always adjacent to three faces and each vertex is formed from three planes at right angles (trihedral). Furthermore, the drawings could only have three kinds of lines: object boundary, concave, and convex. Huffman enumerated all possible configurations of lines around a vertex. This problem was too narrow for real-world situations, so Waltz generalized it to include cracks, shadows, non-trihedral vertices and light. This resulted in over 50 different line labels and thousands of different junctions. [ILD]

## The Waltz Algorithm

- ▷ **Remark**: One of the earliest examples of applied **CSPs**.
- ▷ **Motivation**: Interpret line drawings of **polyhedra**.

- ▷ **Problem**: Are intersections **convex** or **concave**? (interpret  $\hat{=}$  label as such)
- ▷ **Idea**: Adjacent intersections impose **constraints** on each other. Use **CSP** to find a unique set of labelings.

## Waltz Algorithm on Simple Scenes

- ▷ **Assumptions:** All objects
  - ▷ have no shadows or cracks,
  - ▷ have only three-faced vertices,
  - ▷ are in "general position", i.e. no junctions change with small movements of the eye.
- ▷ **Observation 8.2.1.** Then each line on the *images* is one of the following:
  - ▷ a boundary line (edge of an object) ( $<$ ) with right hand of arrow denoting "solid" and left hand denoting "space"
  - ▷ an interior convex edge (label with "+")
  - ▷ an interior concave edge (label with "-")

## 18 Legal Kinds of Junctions

- ▷ **Observation 8.2.2.** There are only 18 "legal" kinds of junctions:

- ▷ **Idea:** given a representation of a diagram
  - ▷ label each junction in one of these manners (lots of possible ways)

▷ junctions must be labeled, so that lines are labeled consistently

▷ **Fun Fact:** CSP always works perfectly! (early success story for CSP [Wal75])

## Waltz's Examples

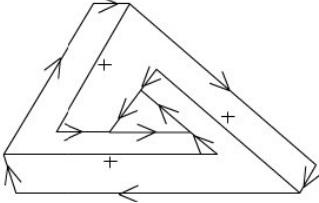

▷ In his dissertation 1972 [Wal75] David Waltz used the following examples

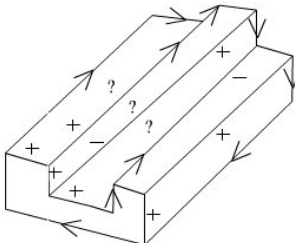

## Waltz Algorithm (More Examples): Ambiguous Figures

### Waltz Algorithm (More Examples): Impossible Figures

**Consistent labelling for impossible figure**

**No consistent labelling possible**

FRIEDRICH-ALEXANDER  
UNIVERSITÄT  
ERLANGEN-NÜRNBERG

2024-02-08

## 8.3 CSP: Towards a Formal Definition

We will now work our way towards a definition of **CSPs** that is formal enough so that we can define the concept of a **solution**. This gives use the necessary grounding to talk about **algorithms** later. **A Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22277>.

### Types of CSPs

- ▷ **Definition 8.3.1.** We call a **CSP discrete**, iff all of the **variables** have **countable domains**; we have two kinds:
  - ▷ **finite domains** (size  $d \rightsquigarrow \mathcal{O}(d^n)$  solutions)
    - ▷ e.g., Boolean **CSPs** (solvability  $\hat{=}$  Boolean satisfiability  $\rightsquigarrow$  NP complete)
  - ▷ **infinite domains** (e.g. integers, strings, etc.)
    - ▷ e.g., job scheduling, **variables** are start/end days for each job
    - ▷ need a "constraint language", e.g.,  $StartJob_1 + 5 \leq StartJob_3$
    - ▷ linear **constraints decidable**, nonlinear ones **undecidable**
- ▷ **Definition 8.3.2.** We call a **CSP continuous**, iff one **domain** is **uncountable**.
- ▷ **Example 8.3.3.** Start/end times for Hubble Telescope observations form a **continuous CSP**.
- ▷ **Theorem 8.3.4.** Linear **constraints solvable** in poly time by **linear programming methods**.

- ▷ **Theorem 8.3.5.** *There cannot be optimal **algorithms** for nonlinear constraint systems.*

## Types of Constraints

- ▷ We classify the **constraints** by the number of **variables** they involve.
- ▷ **Definition 8.3.6.** **Unary constraints** involve a single **variable**, e.g.,  $SA \neq green$ .
- ▷ **Definition 8.3.7.** **Binary constraints** involve pairs of **variables**, e.g.,  $SA \neq WA$ .
- ▷ **Definition 8.3.8.** **Higher-order constraints** involve  $n = 3$  or more **variables**, e.g., cryptarithmic column **constraints**.  
The number  $n$  of **variables** is called the **order** of the **constraint**.
- ▷ **Definition 8.3.9.** **Preferences (soft constraint)** (e.g., **red is better than green**) are often representable by a cost for each **variable** assignment  
 $\leadsto$  **constrained optimization problems**.

## Non-Binary Constraints, e.g. “Send More Money”

- ▷ **Example 8.3.10 (Send More Money).** A student writes home:

$$\begin{array}{r}
 S \ E \ N \ D \\
 + \ M \ O \ R \ E \\
 \hline
 M \ O \ N \ E \ Y
 \end{array}$$

**Puzzle:** letters stand for digits, addition should work out (parents send MONEY€)

- ▷ **Variables:**  $S, E, N, D, M, O, R, Y$ , each with domain  $\{0, \dots, 9\}$ .

- ▷ **Constraints:**

1. all **variables** should have different values:  $S \neq E, S \neq N, \dots$

2. first digits are non-zero:  $S \neq 0, M \neq 0$ .

3. the addition scheme should work out: i.e.

$$1000 \cdot S + 100 \cdot E + 10 \cdot N + D + 1000 \cdot M + 100 \cdot O + 10 \cdot R + E = 10000 \cdot M + 1000 \cdot 0 + 100 \cdot N + 10 \cdot E + Y.$$

**BTW:** The solution is  $S \mapsto 9, E \mapsto 5, N \mapsto 6, D \mapsto 7, M \mapsto 1, O \mapsto 0, R \mapsto 8, Y \mapsto 2 \leadsto$  parents send 10652

- ▷ **Definition 8.3.11.** Problems like the one in Example 8.3.10 are called **crypto arithmetic puzzles**.

## Encoding Higher-Order Constraints as Binary ones

- ▷ **Problem:** The last constraint is of order 8. ( $n = 8$  variables involved)
- ▷ **Observation 8.3.12.** We can write the addition scheme constraint column wise using auxiliary variables, i.e. variables that do not “occur” in the original problem.

$$\begin{array}{rcl}
 D + E & = & Y + 10 \cdot X_1 \\
 X_1 + N + R & = & E + 10 \cdot X_2 \\
 X_2 + E + O & = & N + 10 \cdot X_3 \\
 X_3 + S + M & = & O + 10 \cdot M
 \end{array}
 \qquad
 \begin{array}{r}
 S \quad E \quad N \quad D \\
 + \quad M \quad O \quad R \quad E \\
 \hline
 M \quad O \quad N \quad E \quad Y
 \end{array}$$

These constraints are of order  $\leq 5$ .

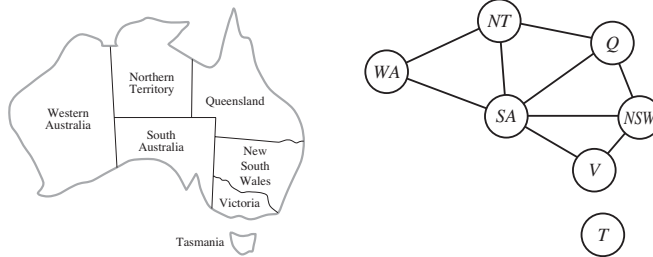

- ▷ **General Recipe:** For  $n \geq 3$ , encode  $C(v_1, \dots, v_{n-1}, v_n)$  as

$$C(p_1(x), \dots, p_{n-1}(x), v_n) \wedge v_1 = p_1(x) \wedge \dots \wedge v_{n-1} = p_{n-1}(x)$$

- ▷ **Problem:** The problem structure gets hidden. (search algorithms can get confused)

## Constraint Graph

- ▷ **Definition 8.3.13.** A binary CSP is a CSP where each constraint is unary or binary.
- ▷ **Observation 8.3.14.** A binary CSP forms a graph called the constraint graph whose nodes are variables, and whose edges represent the constraints.
- ▷ **Example 8.3.15.** Australia as a binary CSP

- ▷ **Intuition:** General-purpose CSP algorithms use the graph structure to speed up search. (E.g., Tasmania is an independent subproblem!)

## Real-world CSPs

- ▷ **Example 8.3.16 (Assignment problems).** e.g., who teaches what class

- ▷ **Example 8.3.17 (Timetabling problems).** e.g., which class is offered when and where?
- ▷ **Example 8.3.18 (Hardware configuration).**
- ▷ **Example 8.3.19 (Spreadsheets).**
- ▷ **Example 8.3.20 (Transportation scheduling).**
- ▷ **Example 8.3.21 (Factory scheduling).**
- ▷ **Example 8.3.22 (Floorplanning).**
- ▷ **Note:** many real-world problems involve real-valued variables  $\leadsto$  continuous CSPs.

## 8.4 Constrain Networks: Formalizing Binary CSPs

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22279>.

### Constraint Networks (Formalizing binary CSPs)

- ▷ **Definition 8.4.1.** A **constraint network** is a triple  $\langle V, D, C \rangle$ , where
  - ▷  $V$  is a **finite** set of **variables**,
  - ▷  $D := \{D_v \mid v \in V\}$  the set of their **domains**, and
  - ▷  $C := \{C_{uv} \subseteq D_u \times D_v \mid u, v \in V \text{ and } u \neq v\}$  is a set of **constraints** with  $C_{uv} = C_{vu}^{-1}$ .

We call the **undirected graph**  $\langle V, \{(u, v) \in V^2 \mid C_{uv} \neq D_u \times D_v\} \rangle$ , the **constraint graph** of  $\gamma$ .
- ▷ We will talk of **CSPs** and mean **constraint networks**.
- ▷ **Remarks:** The **mathematical** formulation gives us a lot of leverage:
  - ▷  $C_{uv} \subseteq D_u \times D_v \hat{=}$  possible assignments to **variables**  $u$  and  $v$
  - ▷ **Relations** are the most general formalization, generally we use **symbolic** formulations, e.g. “ $u = v$ ” for the **relation**  $C_{uv} = \{(a, b) \mid a = b\}$  or “ $u \neq v$ ”.
  - ▷ We can express **unary constraints**  $C_u$  by restricting the **domain** of  $v$ :  $D_v := C_v$ .

### Example: SuDoKu as a Constraint Network

- ▷ **Example 8.4.2 (Formalize SuDoKu).** We use the added formality to encode SuDoKu as a **constraint network**, not just as a **CSP** as Example 8.1.6.

|   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|
| 2 | 5 |   |   | 3 |   | 9 |   | 1 |
|   | 1 |   |   |   | 4 |   |   |   |
| 4 |   | 7 |   |   |   | 2 |   | 8 |
|   |   | 5 | 2 |   |   |   |   |   |
|   |   |   |   | 9 | 8 | 1 |   |   |
|   | 4 |   |   |   | 3 |   |   |   |
|   |   |   | 3 | 6 |   |   | 7 | 2 |
|   | 7 |   |   |   |   |   |   | 3 |
| 9 |   | 3 |   |   |   | 6 |   | 4 |

- ▷ **Variables:**  $V = \{v_{ij} | 1 \leq i, j \leq 9\}$ :  $v_{ij}$  = cell row  $i$  column  $j$ .
- ▷ **Domains** For all  $v \in V$ :  $D_v = D = \{1, \dots, 9\}$ .
- ▷ **Unary constraint:**  $C_{v_{ij}} = \{d\}$  if cell  $i, j$  is pre-filled with  $d$ .
- ▷ **(Binary) constraint:**  $C_{v_{ij}v_{i'j'}} \hat{=} "v_{ij} \neq v_{i'j}"$ , i.e.  
 $C_{v_{ij}v_{i'j'}} = \{(d, d') \in D \times D | d \neq d'\}$ , for:  $i = i'$  (same row), or  $j = j'$  (same column), or  $(\lceil \frac{i}{3} \rceil, \lceil \frac{j}{3} \rceil) = (\lceil \frac{i'}{3} \rceil, \lceil \frac{j'}{3} \rceil)$  (same block).

Note that the ideas are still the same as Example 8.1.6, but in **constraint networks** we have a language to formulate things precisely.

## Constraint Networks (Solutions)

- ▷ Let  $\gamma := \langle V, D, C \rangle$  be a **constraint network**.
- ▷ **Definition 8.4.3.** We call a **partial function**  $a: V \rightarrow \bigcup_{u \in V} D_u$  a **variable assignment** if  $a(v) \in D_v$  for all  $v \in \text{dom}(a)$ .
- ▷ **Definition 8.4.4.** Let  $\mathcal{C} := \langle V, D, C \rangle$  be a **constraint network** and  $a: V \rightarrow \bigcup_{v \in V} D_v$  a **variable assignment**. We say that  $a$  **satisfies** (otherwise **violates**) a **constraint**  $C_{uv}$ , iff  $u, v \in \text{dom}(a)$  and  $(a(u), a(v)) \in C_{uv}$ .  $a$  is called **consistent** in  $\mathcal{C}$ , iff it **satisfies** all **constraints** in  $\mathcal{C}$ . A **value**  $w \in D_u$  is **legal** for a **variable**  $u$  in  $\mathcal{C}$ , iff  $\{(u, w)\}$  is a **consistent assignment** in  $\mathcal{C}$ . A **variable** with **illegal value** under  $a$  is called **conflicted**.
- ▷ **Example 8.4.5.** The **empty assignment**  $\epsilon$  is (trivially) **consistent** in any **constraint network**.
- ▷ **Definition 8.4.6.** Let  $f$  and  $g$  be **variable assignments**, then we say that  $f$  **extends** (or is an **extension of**)  $g$ , iff  $\text{dom}(g) \subset \text{dom}(f)$  and  $f|_{\text{dom}(g)} = g$ .
- ▷ **Definition 8.4.7.** We call a **consistent (total) assignment** a **solution** for  $\gamma$  and  $\gamma$  itself **solvable** or **satisfiable**.

## How it all fits together

- ▷ **Lemma 8.4.8.** *Higher-order constraints can be transformed into equi-satisfiable*

*binary constraints using auxiliary variables.*

- ▷ **Corollary 8.4.9.** Any CSP can be represented by a *constraint network*.
- ▷ **In other words** The notion of a *constraint network* is a refinement of a CSP.
- ▷ So we will stick to *constraint networks* in this course.
- ▷ **Observation 8.4.10.** We can view a *constraint network* as a *search problem*, if we take the *states* as the *variable assignments*, the *actions* as *assignment extensions*, and the *goal states* as *consistent assignments*.
- ▷ **Idea:** We will explore that idea for algorithms that solve constraint networks.

## 8.5 CSP as Search

We now follow up on Observation 8.4.10 to use *search algorithms* for *solving constraint networks*.

The key point of this section is that the *factored states* representations realized by *constraint networks* allow the formulation of very powerful *heuristics*. A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22319>.

### Standard search formulation (incremental)

- ▷ **Idea:** Every *constraint network* induces a *single state problem*.
- ▷ **State** are defined by the *values assigned* so far
  - ▷ **States** are *variable assignments*
  - ▷ **Initial state:** the empty assignment,  $\emptyset$
  - ▷ **Actions:** extend current assignment  $a$  by a pair  $(x, v)$  that does not *conflicted* with  $a$ .
  - ▷  $\leadsto$  fail if no *consistent assignments* exist (**not fixable!**)
  - ▷ **Goal test:** the current assignment is *total*.
- ▷ **Remark:** This is the same for all CSPs! ☹
- ▷ **Observation:** Every *solution* appears at *depth  $n$*  with  $n$  variables.
- ▷ **Idea:** Use *depth first search!*
- ▷ **Path** is irrelevant, so can also use *complete-state formulation*
- ▷ **Branching factor**  $b = (n - \ell)d$  at *depth  $\ell$* , hence  $n!d^n$  *leaves!!!!* ☹

### Backtracking Search

- ▷ **Assignments** for different *variables* are independent!

- ▷ e.g. first WA = red then NT = green vs. first NT = green then WA = red
- ▷  $\rightsquigarrow$  we only need to consider assignments to a single variable at each node
- ▷  $\rightsquigarrow b = d$  and there are  $d^n$  leaves.

- ▷ **Definition 8.5.1.** Depth first search for CSPs with single-variable assignment extensions actions is called **backtracking search**.
- ▷ Backtracking search is the basic uninformed algorithm for CSPs.
- ▷ It can solve the  $n$ -queens problem for  $\cong n = 25$ .

## Backtracking Search (Implementation)

- ▷ **Definition 8.5.2.** The generic backtracking search algorithm

```
procedure Backtracking-Search(csp) returns solution/failure
 return Recursive-Backtracking (\emptyset , csp)
```

```
procedure Recursive-Backtracking (assignment) returns soln/failure
 if assignment is complete then return assignment
 var := Select-Unassigned-Variable(Variables[csp], assignment, csp)
 foreach value in Order-Domain-Values(var, assignment, csp) do
 if value is consistent with assignment given Constraints[csp] then
 add {var = value} to assignment
 result := Recursive-Backtracking(assignment,csp)
 if result \neq failure then return result
 remove {var= value} from assignment
 return failure
```

## Backtracking in Australia

- ▷ **Example 8.5.3.** We apply backtracking search for a map coloring problem:

Step 1:

Step 2:

Step 3:

## Improving Backtracking Efficiency

- ▷ General-purpose methods can give huge gains in speed for **backtracking search**.
- ▷ Answering the following questions well helps find powerful **heuristics**:
  1. Which **variable** should be **assigned** next? (i.e. a **variable ordering heuristic**)
  2. In what order should its **values** be tried? (i.e. a **value ordering heuristic**)
  3. Can we detect inevitable failure early? (for **pruning strategies**)
  4. Can we take advantage of problem structure? ( $\leadsto$  **inference**)
- ▷ **Observation:** Questions 1/2 correspond to the missing subroutines **Select—Unassigned—Variable** and **Order—Domain—Values** from Definition 8.5.2.

## Heuristic: Minimum Remaining Values (Which Variable)

- ▷ **Definition 8.5.4.** The **minimum remaining values (MRV) heuristic** for **backtracking search** always chooses the **variable** with the fewest **legal values**, i.e. a **variable**  $v$  that given an initial **assignment**  $a$  **minimizes**  $\#\{\{d \in D_v \mid a \cup \{v \rightarrow d\} \text{ is consistent}\}\}$ .
- ▷ **Intuition:** By choosing a most constrained **variable**  $v$  first, we reduce the **branching factor** (number of sub trees generated for  $v$ ) and thus reduce the **size** of our search tree.
- ▷ **Extreme case:** If  $\#\{\{d \in D_v \mid a \cup \{v \rightarrow d\} \text{ is consistent}\}\} = 1$ , then the value assignment to  $v$  is forced by our previous choices.
- ▷ **Example 8.5.5.** In step 3 of Example 8.5.3, there is only one remaining value for SA!

## Degree Heuristic (Variable Order Tie Breaker)

- ▷ **Problem:** Need a tie-breaker among **MRV variables!** (there was no preference in step 1,2)
- ▷ **Definition 8.5.6.** The **degree heuristic** in **backtracking search** always chooses a **most constraining variable**, i.e. given an initial assignment  $a$  always pick a variable  $v$  with  $\#\{v \in (V \setminus \text{dom}(a)) \mid C_{uv} \in C\}$  maximal.
- ▷ By choosing a **most constraining variable** first, we detect **inconsistencies** earlier on and thus reduce the **size of our search tree**.
- ▷ **Commonly used strategy combination:** From the set of **most constrained variable**, pick a **most constraining variable**.
- ▷ **Example 8.5.7.**

Degree heuristic: SA = 5, T = 0, all others 2 or 3.

Where in Example 8.5.7 does the **most constraining variable** play a role in the choice? SA (only possible choice), NT (all choices possible except WA, V, T). Where in the illustration does **most constrained variable** play a role in the choice? NT (all choices possible except T), Q (only Q and WA possible).

## Least Constraining Value Heuristic (Value Ordering)

- ▷ **Definition 8.5.8.** Given a **variable**  $v$ , the **least constraining value heuristic** chooses the **least constraining value** for  $v$ : the one that rules out the fewest **values** in the remaining **variables**, i.e. for a given initial **assignment**  $a$  and a chosen **variable**  $v$  pick a value  $d \in D_v$  that **minimizes**  $\#\{e \in D_u \mid u \neq v, C_{uv} \in C, \text{ and } (e, d) \notin C_{uv}\}$
- ▷ By choosing the **least constraining value** first, we increase the chances to not rule out the **solutions** below the current node.
- ▷ **Example 8.5.9.**

▷ Combining these **heuristics** makes **1000 queens** feasible.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 272 2024-02-08

## 8.6 Conclusion & Preview

### Summary & Preview

▷ Summary of “CSP as Search”:

- ▷ **Constraint networks**  $\gamma$  consist of **variables**, associated with **finite domains**, and **constraints** which are **binary relations** specifying permissible **value pairs**.
- ▷ A **variable assignment**  $a$  maps some **variables** to **values**.  $a$  is **consistent** if it complies with all **constraints**. A **consistent total assignment** is a **solution**.
- ▷ The **constraint satisfaction problem (CSP)** consists in finding a **solution** for a **constraint network**. This has numerous applications including, e.g., scheduling and timetabling.
- ▷ **Backtracking search** assigns **variable** one by one, **pruning inconsistent variable assignments**.
- ▷ **Variable orderings** in **backtracking** can dramatically reduce the **size** of the **search tree**. **Value orderings** have this potential (only) in **solvable sub trees**.

▷ **Up next:** **Inference** and **decomposition**, for improved **efficiency**.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 273 2024-02-08

### Suggested Reading:

- *Chapter 6: Constraint Satisfaction Problems*, Sections 6.1 and 6.3, in [RN09].
  - Compared to our treatment of the topic “**Constraint Satisfaction Problems**” (chapter 8 and chapter 9), RN covers much more material, but less formally and in much less detail (in particular, my slides contain many additional in-depth examples). Nice background/additional reading, can’t replace the lecture.
  - Section 6.1: Similar to our “Introduction” and “Constraint Networks”, less/different examples, much less detail, more discussion of extensions/variations.
  - Section 6.3: Similar to my “Naïve Backtracking” and “Variable- and Value Ordering”, with less examples and details; contains part of what we cover in chapter 9 (RN does **inference** first, then **backtracking**). Additional discussion of *backjumping*.

# Chapter 9

## Constraint Propagation

In this chapter we discuss another idea that is central to **symbolic AI** as a whole. The first component is that with the **factored states** representations, we need to use a representation language for (sets of) states. The second component is that instead of state-level search, we can graduate to representation-level search (**inference**), which can be much more **efficient** than state level search as the respective representation language actions correspond to groups of state-level actions.

### 9.1 Introduction

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22321>.

### Illustration: Constraint Propagation

▷ **Example 9.1.1.** A **constraint network**  $\gamma$ :

▷ **Question:** Can we add a **constraint** without losing any **solutions**?

▷ **Example 9.1.2.**  $C_{WAQ} := "="$ . If **WA** and **Q** are **assigned** different colors, then **NT** must be **assigned** the 3rd color, leaving no color for **SA**.

▷ **Intuition:** Adding **constraints** without losing **solutions**  
≙ obtaining an **equivalent network** with a “**tighter description**”  
~ a smaller number of **consistent (partial) variable assignments**  
~ more **efficient** search!

**FAU** FRIEDRICH-ALEXANDER  
UNIVERSITÄT  
ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 274 2024-02-08 

### Illustration: Decomposition

▷ **Example 9.1.3.** **Constraint network**  $\gamma$ :

- ▷ We can separate this into two independent **constraint networks**.
- ▷ Tasmania is not adjacent to any other state. Thus we can color Australia first, and assign an arbitrary color to Tasmania afterwards.
- ▷ Decomposition methods exploit the structure of the **constraint network**. They identify separate parts (sub-networks) whose inter-dependencies are “simple” and can be handled **efficiently**.
- ▷ **Example 9.1.4 (Extreme case)**. No inter-dependencies at all, as for Tasmania above.

## Our Agenda for This Chapter

- ▷ **Constraint propagation**: How does **inference** work in principle? What are relevant practical aspects?
  - ▷ Fundamental concepts underlying **inference**, basic facts about its use.
- ▷ **Forward checking**: What is the simplest instance of **inference**?
  - ▷ Gets us started on this subject.
- ▷ **Arc consistency**: How to make **inferences** between **variables** whose value is not fixed yet?
  - ▷ Details a **state of the art inference** method.
- ▷ **Decomposition**: **Constraint graphs**, and two simple cases
  - ▷ How to capture dependencies in a constraint network? What are “simple cases”?
  - ▷ Basic results on this subject.
- ▷ **Cutset conditioning**: What if we’re not in a simple case?
  - ▷ Outlines the most easily understandable technique for **decomposition** in the general case.

## 9.2 Constraint Propagation/Inference

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22326>.

### Constraint Propagation/Inference: Basic Facts

▷ **Definition 9.2.1.** **Constraint propagation** (i.e. inference in constraint networks) consists in deducing additional constraints, that follow from the already known constraints, i.e. that are satisfied in all solutions.

▷ **Example 9.2.2.** It's what you do all the time when playing SuDoKu:

|   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|
|   | 5 | 8 | 7 |   | 6 | 9 | 4 | 1 |
|   |   | 9 | 8 |   | 4 | 3 | 5 | 7 |
| 4 |   | 7 | 9 |   | 5 | 2 | 6 | 8 |
| 3 | 9 | 5 | 2 | 7 | 1 | 4 | 8 | 6 |
| 7 | 6 | 2 | 4 | 9 | 8 | 1 | 3 | 5 |
| 8 | 4 | 1 | 6 | 5 | 3 | 7 | 2 | 9 |
| 1 | 8 | 4 | 3 | 6 | 9 | 5 | 7 | 2 |
| 5 | 7 | 6 | 1 | 4 | 2 | 8 | 9 | 3 |
| 9 | 2 | 3 | 5 | 8 | 7 | 6 | 1 | 4 |

▷ **Formally:** Replace  $\gamma$  by an equivalent and strictly tighter constraint network  $\gamma'$ .

### Equivalent Constraint Networks

▷ **Definition 9.2.3.** We say that two constraint networks  $\gamma := \langle V, D, C \rangle$  and  $\gamma' := \langle V, D', C' \rangle$  sharing the same set of variables are **equivalent**, (write  $\gamma' \equiv \gamma$ ), if they have the same solutions.

▷ **Example 9.2.4.**

Are these constraint networks equivalent? No.

Are these constraint networks equivalent? Yes.

## Tightness

▷ **Definition 9.2.5 (Tightness).** Let  $\gamma := \langle V, D, C \rangle$  and  $\gamma' = \langle V, D', C' \rangle$  be constraint networks sharing the same set of variables, then  $\gamma'$  is **tighter** than  $\gamma$ , (write  $\gamma' \sqsubseteq \gamma$ ), if:

- (i) For all  $v \in V$ :  $D'_v \subseteq D_v$ .
- (ii) For all  $u \neq v \in V$  and  $C'_{uv} \in C'$ : either  $C'_{uv} \not\subseteq C$  or  $C'_{uv} \subseteq C_{uv}$ .

$\gamma'$  is **strictly tighter** than  $\gamma$ , (written  $\gamma' \sqsubset \gamma$ ), if at least one of these inclusions is proper.

▷ **Example 9.2.6.**

Here, we do have  $\gamma' \sqsubseteq \gamma$ .

Here, we do have  $\gamma' \sqsubseteq \gamma$ .

Here, we do not have  $\gamma' \sqsubseteq \gamma$ !

- ▷ **Intuition:** Strict tightness  $\hat{=}$   $\gamma'$  has the same constraints as  $\gamma$ , plus some.

## Equivalence + Tightness = Inference

- ▷ **Theorem 9.2.7.** Let  $\gamma$  and  $\gamma'$  be constraint networks such that  $\gamma' \hat{=} \gamma$  and  $\gamma' \sqsubseteq \gamma$ . Then  $\gamma'$  has the same solutions as, but fewer consistent assignments than,  $\gamma$ .

- ▷  $\leadsto \gamma'$  is a better encoding of the underlying problem.

- ▷ **Example 9.2.8.** Two equivalent constraint networks (one obviously unsolvable)

$\epsilon$  cannot be extended to a solution (neither in  $\gamma$  nor in  $\gamma'$  because they're equivalent); this is obvious (red  $\neq$  blue) in  $\gamma'$ , but not in  $\gamma$ .

## How to Use Constraint Propagation in CSP Solvers?

- ▷ **Simple:** Constraint propagation as a pre-process:
  - ▷ **When:** Just once before search starts.
  - ▷ **Effect:** Little running time overhead, little pruning power. (not considered here)
- ▷ **More Advanced:** Constraint propagation during search:
  - ▷ **When:** At every recursive call of backtracking.
  - ▷ **Effect:** Strong pruning power, may have large running time overhead.
- ▷ **Search vs. Inference:** The more complex the inference, the smaller the number of search nodes, but the larger the running time needed at each node.
- ▷ **Idea:** Encode variable assignments as unary constraints (i.e., for  $a(v) = d$ , set the unary constraint  $D_v = \{d\}$ ), so that inference reasons about the network restricted to the commitments already made in the search.

▷ **Definition 9.3.3 (Inference, Version 1).** Forward checking implemented

```

function ForwardChecking(γ, a) returns modified γ
 for each v where $a(v) = d'$ is defined do
 for each u where $a(u)$ is undefined and $C_{uv} \in C$ do
 $D_u := \{d \in D_u \mid (d, d') \in C_{uv}\}$
 return γ

```

CC BY-NC-SA

**Note:** It's a bit strange that we start with  $d'$  here; this is to make link to arc consistency – coming up next – as obvious as possible (same notations  $u$ , and  $d$  vs.  $v$  and  $d'$ ).

### Forward Checking: Discussion

- ▷ **Definition 9.3.4.** An inference procedure is called **sound**, iff for any input  $\gamma$  the output  $\gamma'$  have the same solutions.
- ▷ **Lemma 9.3.5.** Forward checking is sound.  
*Proof sketch:* Recall here that the assignment  $a$  is represented as unary constraints inside  $\gamma$ .
- ▷ **Corollary 9.3.6.**  $\gamma$  and  $\gamma'$  are equivalent.
- ▷ **Incremental computation:** Instead of the first for-loop in Definition 9.3.3, use only the inner one every time a new assignment  $a(v) = d'$  is added.
- ▷ **Practical Properties:**
  - ▷ Cheap but useful inference method.
  - ▷ Rarely a good idea to not use forward checking (or a stronger inference method subsuming it).
- ▷ **Up next:** A stronger inference method (subsuming forward checking).

- ▷ **Definition 9.3.7.** Let  $p$  and  $q$  be inference procedures, then  $p$  **subsumes**  $q$ , if  $p(\gamma) \sqsubseteq q(\gamma)$  for any input  $\gamma$ .

## 9.4 Arc Consistency

**Video Nuggets** covering this section can be found at <https://fau.tv/clip/id/22350> and <https://fau.tv/clip/id/22351>.

### When Forward Checking is Not Good Enough

- ▷ **Problem:** Forward checking makes inferences only from assigned to unassigned variables.

- ▷ **Example 9.4.1.**

We could do better here: **value 3** for  $v_2$  is not **consistent** with any remaining value for  $v_3 \rightsquigarrow$  it can be removed!

But **forward checking** does not catch this.

### Arc Consistency: Definition

- ▷ **Definition 9.4.2 (Arc Consistency).** Let  $\gamma := \langle V, D, C \rangle$  be a constraint network.

1. A variable  $u \in V$  is **arc consistent** relative to another variable  $v \in V$  if either  $C_{uv} \notin C$ , or for every value  $d \in D_u$  there exists a value  $d' \in D_v$  such that  $(d, d') \in C_{uv}$ .
2. The constraint network  $\gamma$  is **arc consistent** if every variable  $u \in V$  is arc consistent relative to every other variable  $v \in V$ .

The concept of **arc consistency** concerns both levels.

- ▷ **Intuition:** Arc consistency  $\hat{=}$  for every domain value and constraint, at least one value on the other side of the constraint “works”.
- ▷ **Note** the asymmetry between  $u$  and  $v$ : **arc consistency** is directed.

### Arc Consistency: Example

▷ **Definition 9.4.3 (Arc Consistency).** Let  $\gamma := \langle V, D, C \rangle$  be a constraint network.

1. A variable  $u \in V$  is **arc consistent** relative to another variable  $v \in V$  if either  $C_{uv} \notin C$ , or for every value  $d \in D_u$  there exists a value  $d' \in D_v$  such that  $(d, d') \in C_{uv}$ .
2. The constraint network  $\gamma$  is **arc consistent** if every variable  $u \in V$  is arc consistent relative to every other variable  $v \in V$ .

The concept of **arc consistency** concerns both levels.

▷ **Example 9.4.4 (Arc Consistency).**

▷ **Question:** On top, middle, is  $v_3$  arc consistent relative to  $v_2$ ?

▷ **Answer:** No. For values 1 and 2,  $D_{v_2}$  does not have a value that works.

▷ **Note:** Enforcing arc consistency for one variable may lead to further reductions on another variable!

▷ **Question:** And on the right?

▷ **Answer:** Yes. (But  $v_2$  is not arc consistent relative to  $v_3$ )

### Arc Consistency: Example

▷ **Definition 9.4.5 (Arc Consistency).** Let  $\gamma := \langle V, D, C \rangle$  be a constraint network.

1. A variable  $u \in V$  is **arc consistent** relative to another variable  $v \in V$  if either  $C_{uv} \notin C$ , or for every value  $d \in D_u$  there exists a value  $d' \in D_v$  such that  $(d, d') \in C_{uv}$ .
2. The constraint network  $\gamma$  is **arc consistent** if every variable  $u \in V$  is arc consistent relative to every other variable  $v \in V$ .

The concept of **arc consistency** concerns both levels.

▷ **Example 9.4.6.**

WA NT Q NSW V SA T

~?

▷ **Note:** SA is not arc consistent relative to NT in 3rd row.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 288 2024-02-08

## Enforcing Arc Consistency: General Remarks

- ▷ **Inference, version 2:** “Enforcing Arc Consistency” = removing domain values until  $\gamma$  is arc consistent. (Up next)
- ▷ **Note:** Assuming such an inference method  $AC(\gamma)$ .
- ▷ **Lemma 9.4.7.**  $AC(\gamma)$  is *sound*: guarantees to deliver an equivalent network.
- ▷ *Proof sketch:* If, for  $d \in D_u$ , there does not exist a value  $d' \in D_v$  such that  $(d, d') \in C_{uv}$ , then  $u = d$  cannot be part of any solution.
- ▷ **Observation 9.4.8.**  $AC(\gamma)$  *subsumes forward checking*:  $AC(\gamma) \sqsubseteq \text{ForwardChecking}(\gamma)$ .
- ▷ *Proof:* Recall from slide 279 that  $\gamma' \sqsubseteq \gamma$  means  $\gamma'$  is tighter than  $\gamma$ .
  1. Forward checking removes  $d$  from  $D_u$  only if there is a constraint  $C_{uv}$  such that  $D_v = \{d'\}$  (i.e. when  $v$  was assigned the value  $d'$ ), and  $(d, d') \notin C_{uv}$ .
  2. Clearly, enforcing arc consistency of  $u$  relative to  $v$  removes  $d$  from  $D_u$  as well.

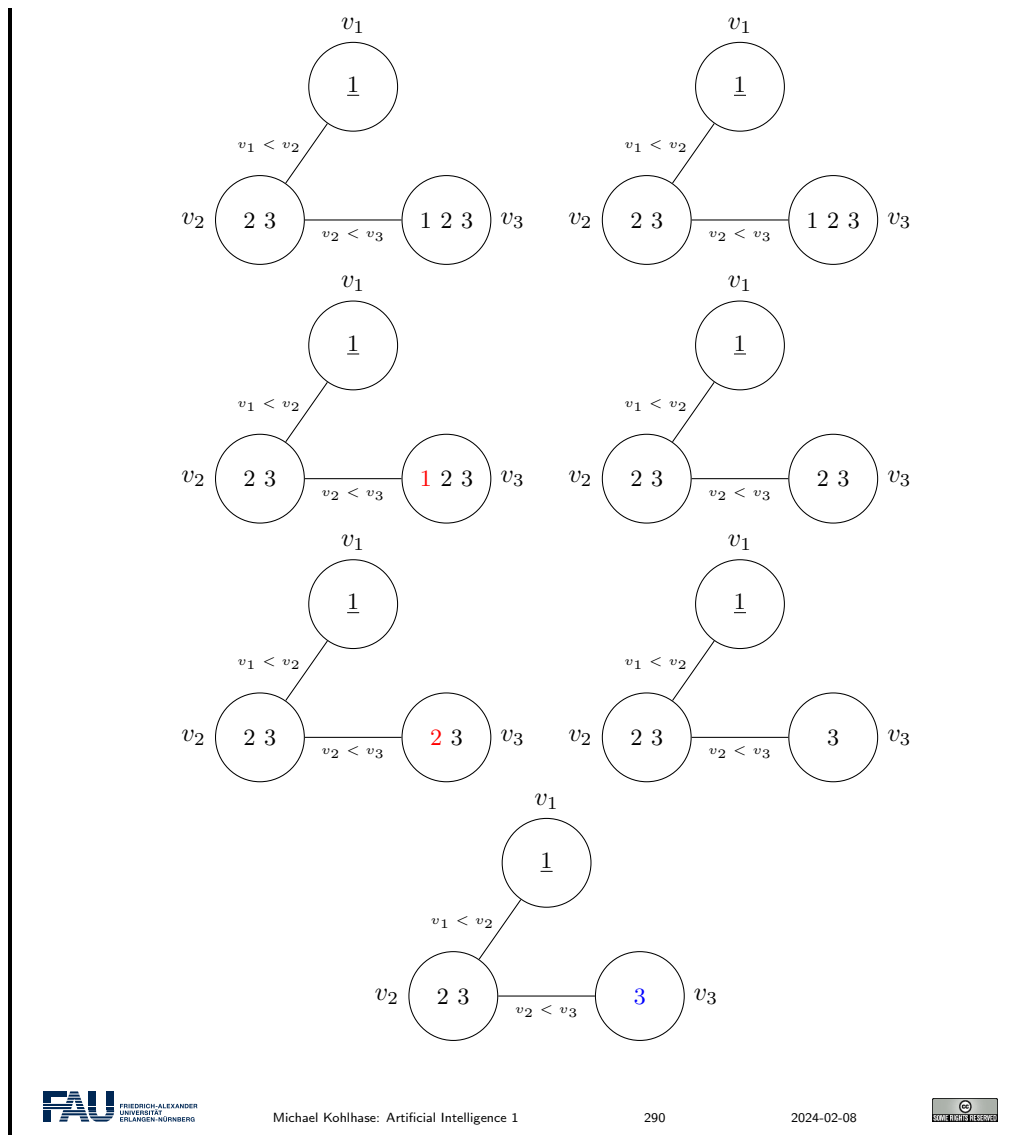

## Enforcing Arc Consistency for One Pair of Variables

- ▷ **Definition 9.4.9 (Revise).** *Revise* is an algorithm enforcing arc consistency of  $u$  relative to  $v$ 

```

function Revise(γ, u, v) returns modified γ
 for each $d \in D_u$ do
 if there is no $d' \in D_v$ with $(d, d') \in C_{uv}$ then $D_u := D_u \setminus \{d\}$
 return γ

```
- ▷ **Lemma 9.4.10.** If  $d$  is maximal domain size in  $\gamma$  and the test “ $(d, d') \in C_{uv}$ ?” has time complexity  $\mathcal{O}(1)$ , then the running time of  $\text{Revise}(\gamma, u, v)$  is  $\mathcal{O}(d^2)$ .
- ▷ **Example 9.4.11.**  $\text{Revise}(\gamma, v_3, v_2)$

## AC-1: Enforcing Arc Consistency (Version 1)

- ▷ **Idea:** Apply **Revise** pairwise up to a **fixed point**.
- ▷ **Definition 9.4.12.** **AC-1** enforces **arc consistency** in **constraint networks**:

```

function AC-1(γ) returns modified γ
 repeat
 changesMade := False
 for each constraint C_{u0v} do
 Revise(γ, u, v) /* if D_u reduces, set changesMade := True */
 Revise(γ, v, u) /* if D_v reduces, set changesMade := True */
 until changesMade = False
 return γ

```

- ▷ **Observation:** Obviously, this does indeed enforce **arc consistency** for  $\gamma$ .

- ▷ **Lemma 9.4.13.** If  $\gamma$  has  $n$  variables,  $m$  constraints, and maximal domain size  $d$ , then the time complexity of  $\text{AC1}(\gamma)$  is  $\mathcal{O}(md^2nd)$ .
- ▷ *Proof sketch:*  $\mathcal{O}(md^2)$  for each inner loop, fixed point reached at the latest once all  $nd$  variable values have been removed.
- ▷ **Problem:** There are redundant computations.
- ▷ **Question:** Do you see what these redundant computations are?
- ▷ **Redundant computations:**  $u$  and  $v$  are revised even if their domains haven't changed since the last time.
- ▷ Better algorithm avoiding this: AC 3 (coming up)

## AC-3: Enforcing Arc Consistency (Version 3)

- ▷ **Idea:** Remember the potentially inconsistent variable pairs.
- ▷ **Definition 9.4.14.** AC-3 optimizes AC-1 for enforcing arc consistency.

```

function AC-3(γ) returns modified γ
 $M := \emptyset$
 for each constraint $C_{uv} \in C$ do
 $M := M \cup \{(u,v), (v,u)\}$
 while $M \neq \emptyset$ do
 remove any element (u,v) from M
 Revise(γ, u, v)
 if D_u has changed in the call to Revise then
 for each constraint $C_{wu} \in C$ where $w \neq v$ do
 $M := M \cup \{(w,u)\}$
 return γ

```

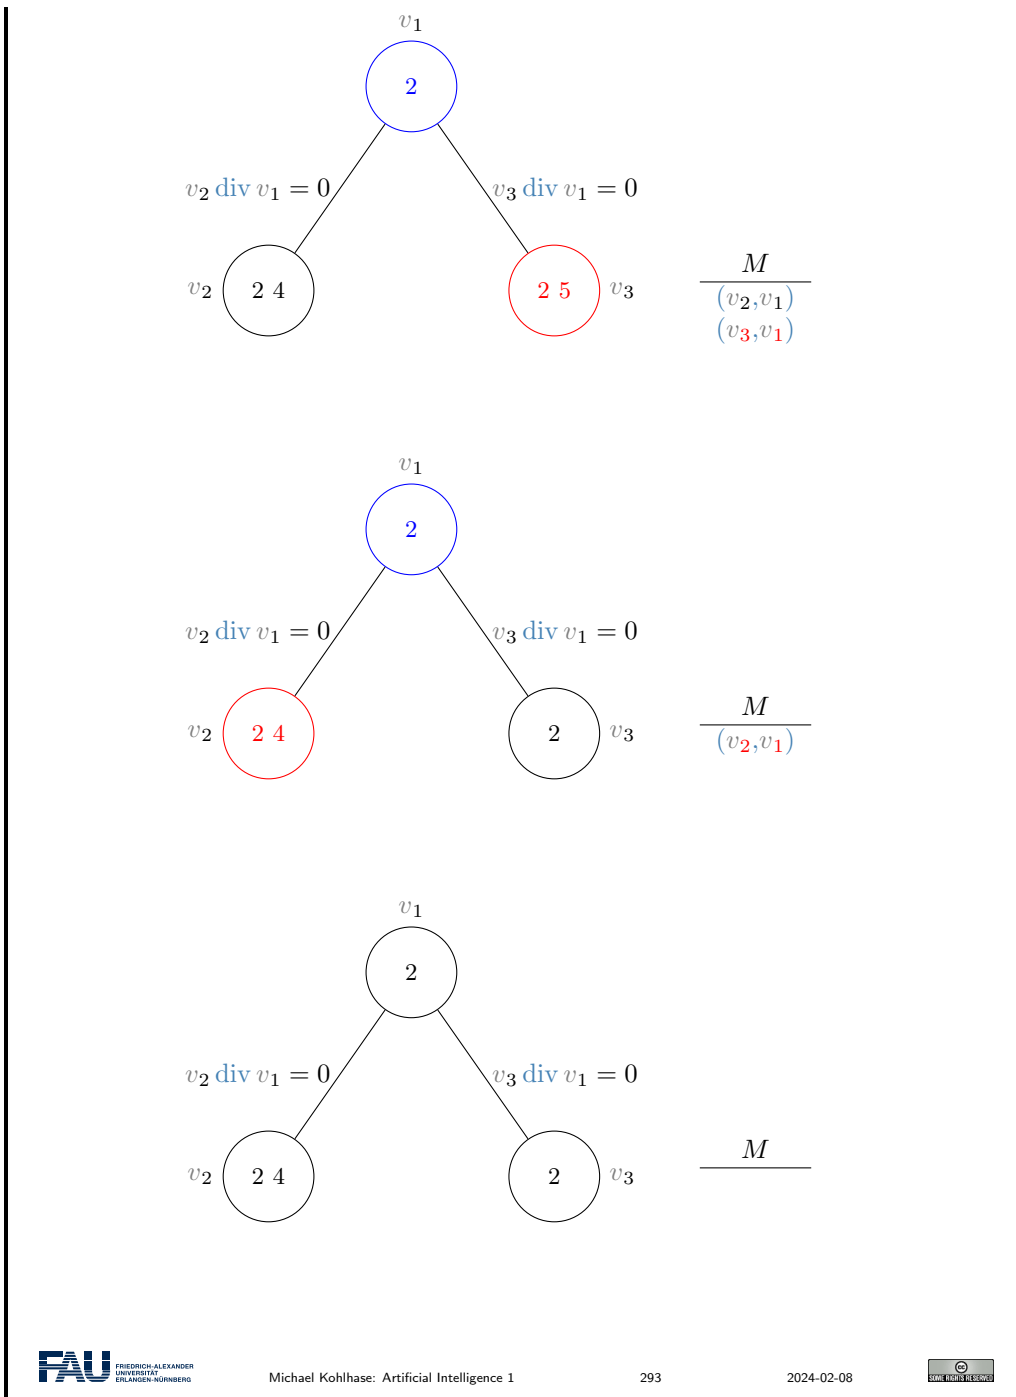

- ▷ **Question:**  $\text{AC-3}(\gamma)$  enforces arc consistency because?
- ▷ **Answer:** At any time during the while-loop, if  $(u,v) \notin M$  then  $u$  is arc consistent relative to  $v$ .
- ▷ **Question:** Why only “where  $w \neq v$ ”?
- ▷ **Answer:** If  $w = v$  is the reason why  $D_u$  changed, then  $w$  is still arc consistent relative to  $u$ : the values just removed from  $D_u$  did not match any values from  $D_w$  anyway.

## AC-3: Example

- ▷ **Example 9.4.15.**  $y \text{ div } x = 0$ :  $y$  modulo  $x$  is 0, i.e.,  $y$  is divisible by  $x$

### AC-3: Runtime

- ▷ **Theorem 9.4.16 (Runtime of AC-3).** Let  $\gamma := \langle V, D, C \rangle$  be a constraint network with  $m$  constraints, and maximal domain size  $d$ . Then  $AC-3(\gamma)$  runs in time  $\mathcal{O}(md^3)$ .
- ▷ *Proof:* by counting how often **Revise** is called.

1. Each call to `Revise( $\gamma, u, v$ )` takes time  $\mathcal{O}(d^2)$  so it suffices to prove that at most  $\mathcal{O}(md)$  of these calls are made.
2. The number of calls to `Revise( $\gamma, u, v$ )` is the number of iterations of the while-loop, which is at most the number of insertions into  $M$ .
3. Consider any constraint  $C_{uv}$ .
4. Two variable pairs corresponding to  $C_{uv}$  are inserted in the for-loop. In the while loop, if a pair corresponding to  $C_{uv}$  is inserted into  $M$ , then
5. beforehand the domain of either  $u$  or  $v$  was reduced, which happens at most  $2d$  times.
6. Thus we have  $\mathcal{O}(d)$  insertions per constraint, and  $\mathcal{O}(md)$  insertions overall, as desired.

## 9.5 Decomposition: Constraint Graphs, and Three Simple Cases

A [Video Nugget](https://fau.tv/clip/id/22353) covering this section can be found at <https://fau.tv/clip/id/22353>.

### Reminder: The Big Picture

- ▷ Say  $\gamma$  is a constraint network with  $n$  variables and maximal domain size  $d$ .
  - ▷  $d^n$  total assignments must be tested in the worst case to solve  $\gamma$ .
- ▷ **Inference:** One method to try to avoid/ameliorate this combinatorial explosion in practice.
  - ▷ Often, from an assignment to some variables, we can easily make inferences regarding other variables.
- ▷ **Decomposition:** Another method to avoid/ameliorate this combinatorial explosion in practice.
  - ▷ Often, we can exploit the structure of a network to decompose it into smaller parts that are easier to solve.
  - ▷ **Question:** What is “structure”, and how to “decompose”?

### Problem Structure

- ▷ **Idea:** Tasmania and mainland are “independent subproblems”
- ▷ **Definition 9.5.1.** Independent subproblems are identified as connected components of constraint graphs.
- ▷ Suppose each independent subproblem has  $c$  variables out of  $n$  total. ( $d$  is max domain size)
- ▷ Worst-case solution cost is  $n \operatorname{div} c \cdot d^c$  (linear in  $n$ )
- ▷ E.g.,  $n = 80, d = 2, c = 20$ 
  - ▷  $2^{80} \hat{=} 4$  billion years at 10 million nodes/sec
  - ▷  $4 \cdot 2^{20} \hat{=} 0.4$  seconds at 10 million nodes/sec

## “Decomposition” 1.0: Disconnected Constraint Graphs

- ▷ **Theorem 9.5.2 (Disconnected Constraint Graphs).** Let  $\gamma := \langle V, D, C \rangle$  be a constraint network. Let  $a_i$  be a solution to each connected component  $\gamma_i$  of the constraint graph of  $\gamma$ . Then  $a := \bigcup_i a_i$  is a solution to  $\gamma$ .
- ▷ *Proof:*
  1.  $a$  satisfies all  $C_{uv}$  where  $u$  and  $v$  are inside the same connected component.
  2. The latter is the case for all  $C_{uv}$ .
  3. If two parts of  $\gamma$  are not connected, then they are independent.
- ▷ **Example 9.5.3.** Color Tasmania separately in Australia

- ▷ **Example 9.5.4 (Doing the Numbers).**
  - ▷  $\gamma$  with  $n = 40$  variables, each domain size  $k = 2$ . Four separate connected components each of size 10.
  - ▷ Reduction of worst-case when using decomposition:
    - ▷ No decomposition:  $2^{40}$ . With:  $4 \cdot 2^{10}$ . Gain:  $2^{28} \approx 280.000.000$ .
- ▷ **Definition 9.5.5.** The process of decomposing a constraint network into components is called decomposition. There are various decomposition algorithms.

## Tree-structured CSPs

- ▷ **Theorem 9.5.6.** If the *constraint graph* has no *cycles*, the *CSP* can be solved in  $\mathcal{O}(nd^2)$  time.
- ▷ Compare to general *CSPs*, where worst case time is  $\mathcal{O}(d^n)$ .
- ▷ This property also applies to *logical* and *probabilistic reasoning*: an important example of the relation between syntactic restrictions and the complexity of *reasoning*.

## Algorithm for tree-structured CSPs

1. Choose a *variable* as root, order *variables* from root to leaves such that every node's parent precedes it in the ordering

2. For  $j$  from  $n$  down to 2, apply  

RemoveInconsistent(Parent( $X_j$ ),  $X_j$ )
3. For  $j$  from 1 to  $n$ , assign  $X_j$  consistently with  $Parent(X_j)$

## Nearly tree-structured CSPs

- ▷ **Definition 9.5.7.** *Conditioning*: instantiate a variable, *prune* its neighbors' domains.
- ▷ **Example 9.5.8.**

▷ **Definition 9.5.9. Cutset conditioning:** instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree.

▷ Cutset size  $c \rightsquigarrow$  running time  $\mathcal{O}(d^c(n - c)d^2)$ , very fast for small  $c$ .

 Michael Kohlhase: Artificial Intelligence 1
 300
2024-02-08

### “Decomposition” 2.0: Acyclic Constraint Graphs

▷ **Theorem 9.5.10 (Acyclic Constraint Graphs).** Let  $\gamma := \langle V, D, C \rangle$  be a constraint network with  $n$  variables and maximal domain size  $k$ , whose constraint graph is acyclic. Then we can find a solution for  $\gamma$ , or prove  $\gamma$  to be unsatisfiable, in time  $\mathcal{O}(nk^2)$ .

▷ *Proof sketch:* See the algorithm on the next slide

▷ Constraint networks with acyclic constraint graphs can be solved in (low order) polynomial time.

▷ **Example 9.5.11.** Australia is not acyclic. (But see next section)

▷ **Example 9.5.12 (Doing the Numbers).**

▷  $\gamma$  with  $n = 40$  variables, each domain size  $k = 2$ . Acyclic constraint graph.

▷ Reduction of worst-case when using decomposition:

▷ No decomposition:  $2^{40}$ .

▷ With decomposition:  $40 \cdot 2^2$ . Gain:  $2^{32}$ .

## Acyclic Constraint Graphs: How To

▷ **Definition 9.5.13.** Algorithm  $\text{AcyclicCG}(\gamma)$ :

1. Obtain a (directed) tree from  $\gamma$ 's constraint graph, picking an arbitrary variable  $v$  as the root, and directing edges outwards.<sup>a</sup>
2. Order the variables topologically, i.e., such that each node is ordered before its children; denote that order by  $v_1, \dots, v_n$ .
3. for  $i := n, n - 1, \dots, 2$  do:
  - (a)  $\text{Revise}(\gamma, v_{\text{parent}(i)}, v_i)$ .
  - (b) if  $D_{v_{\text{parent}(i)}} = \emptyset$  then return "inconsistent"  
Now, every variable is arc consistent relative to its children.
4. Run  $\text{BacktrackingWithInference}$  with forward checking, using the variable order  $v_1, \dots, v_n$ .

▷ **Lemma 9.5.14.** This algorithm will find a solution without ever having to backtrack!

<sup>a</sup>We assume here that  $\gamma$ 's constraint graph is connected. If it is not, do this and the following for each component separately.

## AcyclicCG( $\gamma$ ): Example

▷ **Example 9.5.15 (AcyclicCG() execution).**

Step 4: After  $a(v_1) := 1$  and forward checking.

Step 4: After  $a(v_2) := 2$  and forward checking.

Step 4: After  $a(v_3) := 3$  (and forward checking).

## 9.6 Cutset Conditioning

A Video Nugget covering this section can be found at <https://fau.tv/clip/id/22354>.

## “Almost” Acyclic Constraint Graphs

### ▷ Example 9.6.1 (Coloring Australia).

### ▷ Cutset Conditioning: Idea:

1. Recursive call of backtracking search on  $a$  s.t. the subgraph of the constraint graph induced by  $\{v \in V \mid a(v) \text{ is undefined}\}$  is acyclic.
  - ▷ Then we can solve the remaining sub-problem with `AcyclicCG()`.
2. Choose the variable ordering so that removing the first  $d$  variables renders the constraint graph acyclic.
  - ▷ Then with (1) we won't have to search deeper than  $d \dots!$

## “Decomposition” 3.0: Cutset Conditioning

▷ **Definition 9.6.2 (Cutset).** Let  $\gamma := \langle V, D, C \rangle$  be a constraint network, and  $V_0 \subseteq V$ . Then  $V_0$  is a **cutset** for  $\gamma$  if the subgraph of  $\gamma$ 's constraint graph induced by  $V \setminus V_0$  is acyclic.  $V_0$  is called **optimal** if its size is minimal among all cutsets for  $\gamma$ .

▷ **Definition 9.6.3.** The **cutset conditioning algorithm**, computes an optimal cutset, from  $\gamma$  and an existing cutset  $V_0$ .

**function** `CutsetConditioning( $\gamma, V_0, a$ )` returns a solution, or “inconsistent”

$\gamma' :=$  a copy of  $\gamma$ ;  $\gamma' :=$  `ForwardChecking( $\gamma', a$ )`

**if** ex.  $v$  with  $D_v = \emptyset$  **then return** “inconsistent”

**if** ex.  $v \in V_0$  s.t.  $a(v)$  is undefined **then select** such  $v$

**else**  $a' :=$  `AcyclicCG( $\gamma'$ )`;

**if**  $a' \neq$  “inconsistent” **then return**  $a \cup a'$  **else return** “inconsistent”

**for each**  $d \in$  copy of  $D_v$  **in some order do**

$a' := a \cup \{v = d\}$ ;  $D_v := \{d\}$ ;

$a'' :=$  `CutsetConditioning( $\gamma', V_0, a'$ )`

**if**  $a'' \neq$  “inconsistent” **then return**  $a''$  **else return** “inconsistent”

▷ Forward checking is required so that “ $a \cup \text{AcyclicCG}(\gamma')$ ” is consistent in  $\gamma$ .

▷ **Observation 9.6.4.** Running time is exponential only in  $\#(V_0)$ , not in  $\#(V)$ !

▷ **Remark 9.6.5.** Finding optimal cutsets is NP hard, but good approximations exist.

## 9.7 Constraint Propagation with Local Search

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22355>.

### Iterative algorithms for CSPs

- ▷ Local search algorithms like **hill climbing** and **simulated annealing** typically work with “complete” states, i.e., all **variables** are assigned
- ▷ To apply to **CSPs**: allow states with **unsatisfied constraints**, actions **reassign variable values**.
- ▷ **Variable selection**: Randomly select any **conflicted variable**.
- ▷ **Value selection** by **min conflicts heuristic**: choose **value** that **violates the fewest constraints** i.e., **hill climb** with  $h(n) := \text{total number of violated constraints}$ .

### Example: 4-Queens

- ▷ **States**: 4 **queens** in 4 columns ( $4^4 = 256$  states)
- ▷ **Actions**: Move **queen** in column
- ▷ **Goal state**: No conflicts
- ▷ **Heuristic**:  $h(n) \hat{=} \text{number of conflict}$

### Performance of min-conflicts

- ▷ Given a random initial state, can solve  **$n$ -queens** in almost **constant time** for arbitrary  $n$  with high probability (e.g.,  $n = 10,000,000$ )
- ▷ The same appears to be true for any randomly-generated **CSP** *except* in a narrow range of the ratio

$$R = \frac{\text{number of constraints}}{\text{number of variables}}$$

## 9.8 Conclusion & Summary

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22356>.

### Conclusion & Summary

- ▷  $\gamma$  and  $\gamma'$  are **equivalent** if they have the same **solutions**.  $\gamma'$  is **tighter** than  $\gamma$  if it is more constrained.
- ▷ **Inference** tightens  $\gamma$  without losing **equivalence**, during **backtracking search**. This reduces the amount of search needed; that benefit must be traded off against the **running time** overhead for making the **inferences**.
- ▷ **Forward checking** removes values **conflicting** with an assignment already made.
- ▷ **Arc consistency** removes values that do not comply with any value still available at the other end of a **constraint**. This **subsumes forward checking**.
- ▷ The **constraint graph** captures the dependencies between **variables**. Separate **connected components** can be solved independently. Networks with **acyclic constraint graphs** can be solved in low order **polynomial time**.
- ▷ A **cutset** is a subset of **variables** removing which renders the **constraint graph acyclic**. **Cutset conditioning backtracks** only on such a **cutset**, and solves a sub-problem with **acyclic constraint graph** at each search **leaf**.

### Topics We Didn't Cover Here

- ▷ **Path consistency,  $k$ -consistency**: Generalizes **arc consistency** to **size  $k$**  subsets of **variables**. Path consistency  $\hat{=}$  3-consistency.
- ▷ **Tree decomposition**: Instead of instantiating **variables** until the **leaf nodes** are **trees**, distribute the **variables** and **constraints** over **sub-CSPs** whose connections form a **tree**.
- ▷ **Backjumping**: Like **backtracking search**, but with ability to back up *across several*

levels (to a previous **variable assignment** identified to be responsible for failure).

- ▷ **No-Good Learning:** Inferring additional **constraints** based on information gathered during **backtracking search**.
- ▷ **Local search:** In space of **total** (but not necessarily **consistent**) **assignments**. (E.g., 8 queens in chapter 6)
- ▷ **Tractable CSP:** Classes of **CSPs** that can be solved in **P**.
- ▷ **Global Constraints:** **Constraints** over many/all **variables**, with associated specialized **inference** methods.
- ▷ **Constraint Optimization Problems (COP):** Utility function over **solutions**, need an optimal one.

### Suggested Reading:

- *Chapter 6: Constraint Satisfaction Problems* in [RN09], in particular Sections 6.2, 6.3.2, and 6.5.
  - Compared to our treatment of the topic “**constraint satisfaction problems**” (chapter 8 and chapter 9), RN covers much more material, but less formally and in much less detail (in particular, our slides contain many additional in-depth examples). Nice background/additional reading, can’t replace the lecture.
  - Section 6.3.2: Somewhat comparable to our “**inference**” (except that **equivalence** and **tightness** are not made explicit in RN) together with “**forward checking**”.
  - Section 6.2: Similar to our “**arc consistency**”, less/different examples, much less detail, additional discussion of path consistency and global constraints.
  - Section 6.5: Similar to our “**decomposition**” and “**cutset conditioning**”, less/different examples, much less detail, additional discussion of tree decomposition.

## Part III

# Knowledge and Inference

**A Video Nugget** covering this part can be found at <https://fau.tv/clip/id/22466>.

This part of the course introduces representation languages and inference methods for **structured** state representations for agents: In contrast to the **atomic** and **factored** state representations from ??, we look at state representations where the relations between objects are not determined by the problem statement, but can be determined by inference-based methods, where the knowledge about the environment is represented in a formal language and new knowledge is derived by transforming expressions of this language.

We look at **propositional logic** – a rather weak representation language – and **first-order logic** – a much stronger one – and study the respective inference procedures. In the end we show that computation in **Prolog** is just an inference problem as well.

# Chapter 10

## Propositional Logic & Reasoning, Part I: Principles

### 10.1 Introduction

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/22455>.

### The Wumpus World

|   |        |                      |     |   |
|---|--------|----------------------|-----|---|
| 4 | Stench | Breeze               | PIT |   |
| 3 | Wumpus | Breeze, Stench, Gold | PIT |   |
| 2 | Stench | Breeze               |     |   |
| 1 | START  | Breeze               | PIT |   |
|   | 1      | 2                    | 3   | 4 |

**Definition 10.1.1.** The **Wumpus world** is a simple game where an **agent** explores a cave with 16 **cells** that can contain **pits**, **gold**, and the **Wumpus** with the goal of getting back out alive with the **gold**.

- ▷ **Definition 10.1.2 (Actions).** The **agent** can perform the following **actions**: **goForward**, **turnRight** (by 90°), **turnLeft** (by 90°), **shoot** arrow in direction you're facing (you got exactly one arrow), **grab** an object in current cell, **leave** cave if you're in cell [1, 1].
- ▷ **Definition 10.1.3 (Initial and Terminal States).** Initially, the **agent** is in cell [1, 1] facing east. If the **agent** falls down a **pit** or meets live **Wumpus** it dies.
- ▷ **Definition 10.1.4 (Percepts).** The **agent** can experience the following **percepts**: **stench**, **breeze**, **glitter**, **bump**, **scream**, **none**.
  - ▷ Cell adjacent (i.e. north, south, west, east) to **Wumpus**: **stench** (else: **none**).
  - ▷ Cell adjacent to **pit**: **breeze** (else: **none**).
  - ▷ Cell that contains **gold**: **glitter** (else: **none**).
  - ▷ You walk into a wall: **bump** (else: **none**).
  - ▷ **Wumpus** shot by arrow: **scream** (else: **none**).

 FRIEDRICH-ALEXANDER  
UNIVERSITÄT  
ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 311 2024-02-08 

## Reasoning in the Wumpus World

▷ **Example 10.1.5 (Reasoning in the Wumpus World).** **A:** agent, **V:** visited, **OK:** safe, **P:** pit, **W:** Wumpus, **B:** breeze, **S:** stench, **G:** gold.

|     |     |     |     |
|-----|-----|-----|-----|
| 1,4 | 2,4 | 3,4 | 4,4 |
| 1,3 | 2,3 | 3,3 | 4,3 |
| 1,2 | 2,2 | 3,2 | 4,2 |
| OK  |     |     |     |
| 1,1 | 2,1 | 3,1 | 4,1 |
| OK  | OK  |     |     |

|     |     |     |     |     |     |
|-----|-----|-----|-----|-----|-----|
| 1,4 | 2,4 | 3,4 | 4,4 |     |     |
| 1,3 | 2,3 | 3,3 | 4,3 |     |     |
| 1,2 | 2,2 | P?  | 3,2 | 4,2 |     |
| OK  |     |     |     |     |     |
| 1,1 | 2,1 | A   | 3,1 | P?  | 4,1 |
| V   | OK  | B   | OK  |     |     |

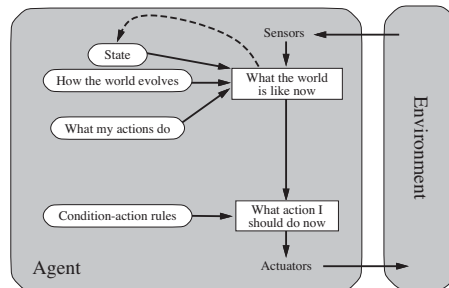

|     |     |     |     |     |    |     |
|-----|-----|-----|-----|-----|----|-----|
| 1,4 | 2,4 | 3,4 | 4,4 |     |    |     |
| 1,3 | W!  | 2,3 | 3,3 | 4,3 |    |     |
| 1,2 | A   | 2,2 | 3,2 | 4,2 |    |     |
| S   | OK  |     |     |     |    |     |
| 1,1 | V   | 2,1 | B   | 3,1 | P! | 4,1 |
| V   | OK  | V   | OK  |     |    |     |

(1) Initial state      (2) One step to right      (3) Back, and up to [1,2]

- ▷ *The Wumpus is in [1,3]!* How do we know?
- ▷ No stench in [2,1], so the stench in [1,2] can only come from [1,3].
- ▷ *There's a pit in [3,1]!* How do we know?
- ▷ No breeze in [1,2], so the breeze in [2,1] can only come from [3,1].

## Agents that Think Rationally

- ▷ **Idea:** Think Before You Act!  
 "Thinking" = Inference about knowledge represented using logic.
- ▷ **Definition 10.1.6.** A logic-based agent is a model-based agent that represents the world state as a logical formula and uses inference to think about the state of the environment and its own actions.

```

function KB-AGENT (percept) returns an action
 persistent: KB, a knowledge base
 t, a counter, initially 0, indicating time
 TELL(KB, MAKE-PERCEPT-SENTENCE(percept,t))
 action := ASK(KB, MAKE-ACTION-QUERY(t))
 TELL(KB, MAKE-ACTION-SENTENCE(action,t))
 t := t+1
 return action

```

## Logic: Basic Concepts (Representing Knowledge)

- ▷ **Definition 10.1.7. Syntax:** What are legal statements (**formulae**) **A** in the logic?
- ▷ **Example 10.1.8.** “*W*” and “ $W \Rightarrow S$ ”. ( $W \hat{=} \text{Wumpus is here}$ ,  $S \hat{=} \text{it stinks}$ )
- ▷ **Definition 10.1.9. Semantics:** Which formulas **A** are true under which **assignment**  $\varphi$ , written  $\varphi \models A$ ?
- ▷ **Example 10.1.10.** If  $\varphi := \{W \mapsto T, S \mapsto F\}$ , then  $\varphi \models W$  but  $\varphi \not\models W \Rightarrow S$ .
- ▷ **Intuition:** Knowledge about the state of the world is described by **formulae**, **interpretations** evaluate them in the current world (**they should turn out true!**)

## Logic: Basic Concepts (Reasoning about Knowledge)

- ▷ **Definition 10.1.11. Entailment:** Which **B** follow from **A**, written  $A \models B$ , meaning that, for all  $\varphi$  with  $\varphi \models A$ , we have  $\varphi \models B$ ? E.g.,  $P \wedge (P \Rightarrow Q) \models Q$ .
- ▷ **Intuition:** **Entailment**  $\hat{=}$  ideal outcome of reasoning, everything that we can possibly conclude. e.g. determine **Wumpus** position as soon as we have enough information
- ▷ **Definition 10.1.12. Deduction:** Which statements **B** can be **derived** from **A** using a set **C** of **inference rules** (a **calculus**), written  $A \vdash_C B$ ?
- ▷ **Example 10.1.13.** If **C** contains  $\frac{A \quad A \Rightarrow B}{B}$  then  $P, P \Rightarrow Q \vdash_C Q$
- ▷ **Intuition:** **Deduction**  $\hat{=}$  process in an actual **computer** trying to reason about **entailment**. E.g. a mechanical process attempting to determine **Wumpus** position.
- ▷ **Definition 10.1.14. Soundness:** whenever  $A \vdash_C B$ , we also have  $A \models B$ .
- ▷ **Definition 10.1.15. Completeness:** whenever  $A \models B$ , we also have  $A \vdash_C B$ .

## General Problem Solving using Logic

- ▷ **Idea:** Any problem that can be formulated as reasoning about logic.  $\rightsquigarrow$  use off-the-shelf reasoning tool.
- ▷ Very successful using **propositional logic** and modern **SAT solvers!** (**Propositional satisfiability testing; chapter 13**)

## Propositional Logic and Its Applications

- ▷ **Propositional logic** = canonical form of knowledge + reasoning.
  - ▷ Syntax: Atomic propositions that can be either true or false, connected by “and, or, and not”.
  - ▷ Semantics: Assign value to every proposition, evaluate connectives.
- ▷ **Applications:** Despite its simplicity, widely applied!
  - ▷ **Product configuration** (e.g., Mercedes). Check consistency of customized combinations of components.
  - ▷ **Hardware verification** (e.g., Intel, AMD, IBM, Infineon). Check whether a circuit has a desired property  $p$ .
  - ▷ **Software verification:** Similar.
  - ▷ **CSP applications:** propositional logic can be (successfully!) used to formulate and solve constraint satisfaction problems. (see chapter 8)
- ▷ chapter 9 gives an example for verification.

## Our Agenda for This Topic

- ▷ **This section:** Basic definitions and concepts; tableaux, resolution.
  - ▷ Sets up the framework. Resolution is the quintessential reasoning procedure underlying most successful SAT solvers.
- ▷ **Next Section (chapter 13):** The Davis Putnam procedure and clause learning; practical problem structure.
  - ▷ State-of-the-art algorithms for reasoning about propositional logic, and an important observation about how they behave.

## Our Agenda for This Chapter

- ▷ **Propositional logic:** What's the syntax and semantics? How can we capture deduction?
  - ▷ We study this logic formally.
- ▷ **Tableaux, Resolution:** How can we make deduction mechanizable? What are its properties?
  - ▷ Formally introduces the most basic machine-oriented reasoning methods.
- ▷ **Killing a Wumpus:** How can we use all this to figure out where the Wumpus is?

▷ Coming back to our introductory example.

## 10.2 Propositional Logic (Syntax/Semantics)

**Video Nuggets** covering this section can be found at <https://fau.tv/clip/id/22457> and <https://fau.tv/clip/id/22458>.

### Propositional Logic (Syntax)

▷ **Definition 10.2.1 (Syntax).** The **formulae** of **propositional logic** (write  $PL^0$ ) are made up from

- ▷ **propositional variables:**  $\mathcal{V}_0 := \{P, Q, R, P^1, P^2, \dots\}$  (countably infinite)
- ▷ A **propositional signature:** constants/constructors called **connectives:**  $\Sigma_0 := \{T, F, \neg, \vee, \wedge, \Rightarrow, \Leftrightarrow, \dots\}$

We define the set  $wff_0(\mathcal{V}_0)$  of **well-formed propositional formula (wffs)** as

- ▷ **propositional variables,**
- ▷ **the logical constants  $T$  and  $F$ ,**
- ▷ **negations  $\neg A$ ,**
- ▷ **conjunctions  $A \wedge B$  ( $A$  and  $B$  are called **conjuncts**),**
- ▷ **disjunctions  $A \vee B$  ( $A$  and  $B$  are called **disjuncts**),**
- ▷ **implications  $A \Rightarrow B$ , and**
- ▷ **equivalences (or **biimplication**).  $A \Leftrightarrow B$ ,**

where  $A, B \in wff_0(\mathcal{V}_0)$  themselves.

▷ **Example 10.2.2.**  $P \wedge Q, P \vee Q, (\neg P \vee Q) \Leftrightarrow (P \Rightarrow Q) \in wff_0(\mathcal{V}_0)$

▷ **Definition 10.2.3.** **Propositional formulae** without **connectives** are called **atomic** (or an **atom**) and **complex** otherwise.

### Propositional Logic Grammar Overview

▷ **Grammar for Propositional Logic:**

|                         |                                                   |             |
|-------------------------|---------------------------------------------------|-------------|
| propositional variables | $X ::= \mathcal{V}_0 = \{P, Q, R, \dots, \dots\}$ | variables   |
| propositional formulae  | $A ::= X$                                         | variable    |
|                         | $\neg A$                                          | negation    |
|                         | $A_1 \wedge A_2$                                  | conjunction |
|                         | $A_1 \vee A_2$                                    | disjunction |
|                         | $A_1 \Rightarrow A_2$                             | implication |
|                         | $A_1 \Leftrightarrow A_2$                         | equivalence |

## Alternative Notations for Connectives

| Here                  | Elsewhere                          |
|-----------------------|------------------------------------|
| $\neg A$              | $\sim A$ $\bar{A}$                 |
| $A \wedge B$          | $A \& B$ $A \bullet B$ $A, B$      |
| $A \vee B$            | $A + B$ $A   B$ $A ; B$            |
| $A \Rightarrow B$     | $A \rightarrow B$ $A \supset B$    |
| $A \Leftrightarrow B$ | $A \leftrightarrow B$ $A \equiv B$ |
| $F$                   | $\perp$ $0$                        |
| $T$                   | $\top$ $1$                         |

## Semantics of $PL^0$ (Models)

▷ **Definition 10.2.4.** A **model**  $\mathcal{M} := \langle \mathcal{D}_o, \mathcal{I} \rangle$  for **propositional logic** consists of

- ▷ the **universe**  $\mathcal{D}_o = \{T, F\}$
- ▷ the **interpretation**  $\mathcal{I}$  that **assigns values** to essential **connectives**.
- ▷  $\mathcal{I}(\neg): \mathcal{D}_o \rightarrow \mathcal{D}_o; T \mapsto F, F \mapsto T$
- ▷  $\mathcal{I}(\wedge): \mathcal{D}_o \times \mathcal{D}_o \rightarrow \mathcal{D}_o; \langle \alpha, \beta \rangle \mapsto T$ , iff  $\alpha = \beta = T$

We call a constructor a **logical constant**, iff its **value** is fixed by the **interpretation**.

▷ Treat the other **connectives** as abbreviations, e.g.  $A \vee B \hat{=} \neg(\neg A \wedge \neg B)$  and  $A \Rightarrow B \hat{=} \neg A \vee B$ , and  $T \hat{=} P \vee \neg P$  **(only need to treat  $\neg, \wedge$  directly)**

## Semantics of $PL^0$ (Evaluation)

▷ **Problem:** The **interpretation function** only **assigns meaning** to **connectives**.

▷ **Definition 10.2.5.** A **variable assignment**  $\varphi: \mathcal{V}_0 \rightarrow \mathcal{D}_o$  **assigns values** to **propositional variables**.

▷ **Definition 10.2.6.** The **value function**  $\mathcal{I}_\varphi: \text{wff}_0(\mathcal{V}_0) \rightarrow \mathcal{D}_o$  **assigns values** to  **$PL^0$  formulae**. It is recursively defined,

- ▷  $\mathcal{I}_\varphi(P) = \varphi(P)$  (base case)
- ▷  $\mathcal{I}_\varphi(\neg A) = \mathcal{I}(\neg)(\mathcal{I}_\varphi(A))$ .
- ▷  $\mathcal{I}_\varphi(A \wedge B) = \mathcal{I}(\wedge)(\mathcal{I}_\varphi(A), \mathcal{I}_\varphi(B))$ .

- ▷ Note that  $\mathcal{I}_\varphi(\mathbf{A} \vee \mathbf{B}) = \mathcal{I}_\varphi(\neg(\neg\mathbf{A} \wedge \neg\mathbf{B}))$  is only determined by  $\mathcal{I}_\varphi(\mathbf{A})$  and  $\mathcal{I}_\varphi(\mathbf{B})$ , so we think of the defined connectives as **logical constants** as well.
- ▷ **Definition 10.2.7.** Two formulae **A** and **B** are called **equivalent**, iff  $\mathcal{I}_\varphi(\mathbf{A}) = \mathcal{I}_\varphi(\mathbf{B})$  for all variable assignments  $\varphi$ .

## Computing Semantics

- ▷ **Example 10.2.8.** Let  $\varphi := [\mathbf{T}/P_1], [\mathbf{F}/P_2], [\mathbf{T}/P_3], [\mathbf{F}/P_4], \dots$  then

$$\begin{aligned}
 & \mathcal{I}_\varphi(P_1 \vee P_2 \vee \neg(\neg P_1 \wedge P_2) \vee P_3 \wedge P_4) \\
 = & \mathcal{I}(\vee)(\mathcal{I}_\varphi(P_1 \vee P_2), \mathcal{I}_\varphi(\neg(\neg P_1 \wedge P_2) \vee P_3 \wedge P_4)) \\
 = & \mathcal{I}(\vee)(\mathcal{I}(\vee)(\mathcal{I}_\varphi(P_1), \mathcal{I}_\varphi(P_2)), \mathcal{I}(\vee)(\mathcal{I}_\varphi(\neg(\neg P_1 \wedge P_2)), \mathcal{I}_\varphi(P_3 \wedge P_4))) \\
 = & \mathcal{I}(\vee)(\mathcal{I}(\vee)(\varphi(P_1), \varphi(P_2)), \mathcal{I}(\vee)(\mathcal{I}(\neg)(\mathcal{I}_\varphi(\neg P_1 \wedge P_2)), \mathcal{I}(\wedge)(\mathcal{I}_\varphi(P_3), \mathcal{I}_\varphi(P_4)))) \\
 = & \mathcal{I}(\vee)(\mathcal{I}(\vee)(\mathbf{T}, \mathbf{F}), \mathcal{I}(\vee)(\mathcal{I}(\neg)(\mathcal{I}(\wedge)(\mathcal{I}_\varphi(\neg P_1), \mathcal{I}_\varphi(P_2))), \mathcal{I}(\wedge)(\varphi(P_3), \varphi(P_4)))) \\
 = & \mathcal{I}(\vee)(\mathbf{T}, \mathcal{I}(\vee)(\mathcal{I}(\neg)(\mathcal{I}(\wedge)(\mathcal{I}(\neg)(\mathcal{I}_\varphi(P_1)), \varphi(P_2))), \mathcal{I}(\wedge)(\mathbf{T}, \mathbf{F}))) \\
 = & \mathcal{I}(\vee)(\mathbf{T}, \mathcal{I}(\vee)(\mathcal{I}(\neg)(\mathcal{I}(\wedge)(\mathcal{I}(\neg)(\varphi(P_1)), \mathbf{F})), \mathbf{F})) \\
 = & \mathcal{I}(\vee)(\mathbf{T}, \mathcal{I}(\vee)(\mathcal{I}(\neg)(\mathcal{I}(\wedge)(\mathcal{I}(\neg)(\mathbf{T}, \mathbf{F})), \mathbf{F})) \\
 = & \mathcal{I}(\vee)(\mathbf{T}, \mathcal{I}(\vee)(\mathcal{I}(\neg)(\mathcal{I}(\wedge)(\mathbf{F}, \mathbf{F})), \mathbf{F})) \\
 = & \mathcal{I}(\vee)(\mathbf{T}, \mathcal{I}(\vee)(\mathcal{I}(\neg)(\mathbf{F}), \mathbf{F})) \\
 = & \mathcal{I}(\vee)(\mathbf{T}, \mathcal{I}(\vee)(\mathbf{T}, \mathbf{F})) \\
 = & \mathcal{I}(\vee)(\mathbf{T}, \mathbf{T}) \\
 = & \mathbf{T}
 \end{aligned}$$

- ▷ **What a mess!**

Now we will also review some propositional **identities** that will be useful later on. Some of them we have already seen, and some are new. All of them can be proven by simple **truth table** arguments.

## Propositional Identities

- ▷ We have the following **identities** in **propositional logic**:

| Name            | for $\wedge$                                                                         | for $\vee$                                                                                    |
|-----------------|--------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| Idempotence     | $\varphi \wedge \varphi = \varphi$                                                   | $\varphi \vee \varphi = \varphi$                                                              |
| Identity        | $\varphi \wedge \mathbf{T} = \varphi$                                                | $\varphi \vee \mathbf{F} = \varphi$                                                           |
| Absorption I    | $\varphi \wedge \mathbf{F} = \mathbf{F}$                                             | $\varphi \vee \mathbf{T} = \mathbf{T}$                                                        |
| Commutativity   | $\varphi \wedge \psi = \psi \wedge \varphi$                                          | $\varphi \vee \psi = \psi \vee \varphi$                                                       |
| Associativity   | $\varphi \wedge (\psi \wedge \theta) = (\varphi \wedge \psi) \wedge \theta$          | $\varphi \vee (\psi \vee \theta) = (\varphi \vee \psi) \vee \theta$                           |
| Distributivity  | $\varphi \wedge (\psi \vee \theta) = \varphi \wedge \psi \vee \varphi \wedge \theta$ | $\varphi \vee \psi \wedge \theta = (\varphi \vee \psi) \wedge (\varphi \vee \theta)$          |
| Absorption II   | $\varphi \wedge (\varphi \vee \theta) = \varphi$                                     | $\varphi \vee \varphi \wedge \theta = \varphi$                                                |
| De Morgan       | $\neg(\varphi \wedge \psi) = \neg\varphi \vee \neg\psi$                              | $\neg(\varphi \vee \psi) = \neg\varphi \wedge \neg\psi$                                       |
| Double negation | $\neg\neg\varphi = \varphi$                                                          |                                                                                               |
| Definitions     | $\varphi \Rightarrow \psi = \neg\varphi \vee \psi$                                   | $\varphi \Leftrightarrow \psi = (\varphi \Rightarrow \psi) \wedge (\psi \Rightarrow \varphi)$ |

We will now use the distribution of **values** of a propositional formula under all **variable assignments**

to characterize them semantically. The intuition here is that we want to understand theorems, examples, counterexamples, and inconsistencies in **mathematics** and everyday reasoning<sup>1</sup>.

The idea is to use the formal language of propositional formulae as a model for **mathematical** language. Of course, we cannot express all of **mathematics** as Boolean formulae, but we can at least study the interplay of **mathematical** statements (which can be true or false) with the copula “and”, “or” and “not”.

### Semantic Properties of Propositional Formulae

- ▷ **Definition 10.2.9.** Let  $\mathcal{M} := \langle \mathcal{U}, \mathcal{I} \rangle$  be our **model**, then we call **A**
  - ▷ **true under  $\varphi$**  ( $\varphi$  **satisfies A**) in  $\mathcal{M}$ , iff  $\mathcal{I}_\varphi(\mathbf{A}) = \mathbf{T}$ , (write  $\mathcal{M} \models^\varphi \mathbf{A}$ )
  - ▷ **false under  $\varphi$**  ( $\varphi$  **falsifies A**) in  $\mathcal{M}$ , iff  $\mathcal{I}_\varphi(\mathbf{A}) = \mathbf{F}$ , (write  $\mathcal{M} \not\models^\varphi \mathbf{A}$ )
  - ▷ **satisfiable in  $\mathcal{M}$** , iff  $\mathcal{I}_\varphi(\mathbf{A}) = \mathbf{T}$  for some assignment  $\varphi$ ,
  - ▷ **valid in  $\mathcal{M}$** , iff  $\mathcal{M} \models^\varphi \mathbf{A}$  for all **variable assignments**  $\varphi$ ,
  - ▷ **falsifiable in  $\mathcal{M}$** , iff  $\mathcal{I}_\varphi(\mathbf{A}) = \mathbf{F}$  for some **assignments**  $\varphi$ , and
  - ▷ **unsatisfiable in  $\mathcal{M}$** , iff  $\mathcal{I}_\varphi(\mathbf{A}) = \mathbf{F}$  for all **assignments**  $\varphi$ .
- ▷ **Example 10.2.10.**  $x \vee x$  is **satisfiable** and **falsifiable**.
- ▷ **Example 10.2.11.**  $x \vee \neg x$  is **valid** and  $x \wedge \neg x$  is **unsatisfiable**.
- ▷ **Alternative Notation:** Write  $[\mathbf{A}]_\varphi^{\mathcal{I}}$  for  $\mathcal{I}_\varphi(\mathbf{A})$ , if  $\mathcal{M} = \langle \mathcal{U}, \mathcal{I} \rangle$ . (and  $[\mathbf{A}]^{\mathcal{I}}$ , if **A** is ground, and  $[\mathbf{A}]^{\mathcal{I}}$ , if  $\mathcal{M}$  is clear)
- ▷ **Definition 10.2.12 (Entailment).** (aka. **logical consequence**)  
We say that **A entails B** ( $\mathbf{A} \models \mathbf{B}$ ), iff  $\mathcal{I}_\varphi(\mathbf{B}) = \mathbf{T}$  for all  $\varphi$  with  $\mathcal{I}_\varphi(\mathbf{A}) = \mathbf{T}$  (i.e. **all assignments that make A true also make B true**)

Let us now see how these semantic properties model **mathematical** practice.

In **mathematics** we are interested in assertions that are true in all circumstances. In our model of **mathematics**, we use **variable assignments** to stand for “circumstances”. So we are interested in propositional formulae which are true under all **variable assignments**; we call them **valid**. We often give examples (or show situations) which make a conjectured formula false; we call such examples counterexamples, and such assertions **falsifiable**. We also often give examples for certain formulae to show that they can indeed be made true (which is not the same as being **valid** yet); such assertions we call **satisfiable**. Finally, if a formula cannot be made true in any circumstances we call it **unsatisfiable**; such assertions naturally arise in **mathematical** practice in the form of refutation proofs, where we show that an assertion (usually the negation of the theorem we want to prove) leads to an obviously **unsatisfiable** conclusion, showing that the **negation** of the theorem is **unsatisfiable**, and thus the **theorem valid**.

### A better mouse-trap: Truth Tables

<sup>1</sup>Here (and elsewhere) we will use **mathematics** (and the language of **mathematics**) as a test tube for understanding reasoning, since mathematics has a long history of studying its own reasoning processes and assumptions.

▷ Truth tables visualize truth functions:

|        |   |
|--------|---|
| $\neg$ |   |
| T      | F |
| F      | T |

|          |   |   |
|----------|---|---|
| $\wedge$ | T | F |
| T        | T | F |
| F        | F | F |

|        |   |   |
|--------|---|---|
| $\vee$ | T | F |
| T      | T | T |
| F      | T | F |

▷ If we are interested in values for all assignments (e.g.  $z \wedge x \vee \neg(z \wedge y)$ )

| assignments |     |     | intermediate results |                   |                     | full           |
|-------------|-----|-----|----------------------|-------------------|---------------------|----------------|
| $x$         | $y$ | $z$ | $e_1 := z \wedge y$  | $e_2 := \neg e_1$ | $e_3 := z \wedge x$ | $e_3 \vee e_2$ |
| F           | F   | F   | F                    | T                 | F                   | T              |
| F           | F   | T   | F                    | T                 | F                   | T              |
| F           | T   | F   | F                    | T                 | F                   | T              |
| F           | T   | T   | T                    | F                 | F                   | F              |
| T           | F   | F   | F                    | T                 | F                   | T              |
| T           | F   | T   | F                    | T                 | T                   | T              |
| T           | T   | F   | F                    | T                 | F                   | T              |
| T           | T   | T   | T                    | F                 | T                   | T              |

## Hair Color in Propositional Logic

▷ There are three persons, Stefan, Nicole, and Jochen.

1. Their hair colors are black, red, or green.
2. Their study subjects are AI, Physics, or Chinese at least one studies AI.
  - (a) Persons with red or green hair do not study AI.
  - (b) Neither the Physics nor the Chinese students have black hair.
  - (c) Of the two male persons, one studies Physics, and the other studies Chinese.

▷ **Question:** Who studies AI?  
 (A) Stefan (B) Nicole (C) Jochen (D) Nobody

▷ **Answer:** You can solve this using  $PI^0$ , if we accept  $bla(S)$ , etc. as propositional variables.

We first express what we know: For every  $x \in \{S, N, J\}$  (Stefan, Nicole, Jochen) we have

1.  $bla(x) \vee red(x) \vee gre(x)$ ; (note: three formulae)
2.  $ai(x) \vee phy(x) \vee chi(x)$  and  $ai(S) \vee ai(N) \vee ai(J)$ 
  - (a)  $ai(x) \Rightarrow \neg red(x) \wedge \neg gre(x)$ .
  - (b)  $phy(x) \Rightarrow \neg bla(x)$  and  $chi(x) \Rightarrow \neg bla(x)$ .
  - (c)  $phy(S) \wedge chi(J) \vee phy(J) \wedge chi(S)$ .

Now, we obtain new knowledge via **entailment** steps:

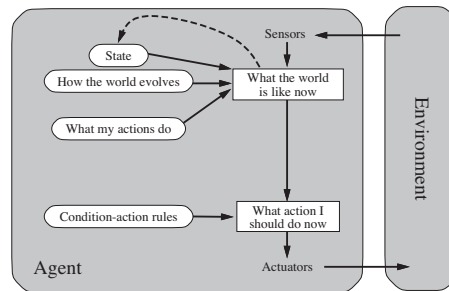

3. 1. together with 2.1 entails that  $ai(x) \Rightarrow bla(x)$  for every  $x \in \{S, N, J\}$ ,
4. thus  $\neg bla(S) \wedge \neg bla(J)$  by 3. and 2.2 and
5. so  $\neg ai(S) \wedge \neg ai(J)$  by 3. and 4.
6. With 2.3 the latter entails  $ai(N)$ .

## 10.3 Inference in Propositional Logics

We have now defined syntax (the language agents can use to represent knowledge) and its semantics (how expressions of this language relate to the world the agent's environment). Theoretically, an agent could use the **entailment relation** to derive new knowledge percepts and the existing state representation – in the MAKE-PERCEPT-SENTENCE and MAKE-ACTION-SENTENCE subroutines below. But as we have seen in above, this is very tedious. A much better way would be to have a set of rules that directly act on the state representations.

## Agents that Think Rationally

- ▷ **Idea:** Think Before You Act!  
“Thinking” = Inference about knowledge represented using logic.
- ▷ **Definition 10.3.1.** A **logic-based agent** is a **model-based agent** that represents the world state as a **logical formula** and uses **inference** to think about the **state** of the **environment** and its own **actions**.

**function** KB-AGENT (*percept*) **returns** an action

**persistent:**  $KB$ , a knowledge base

$t$ , a counter, initially 0, indicating time

TELL( $KB$ , MAKE-PERCEPT-SENTENCE(*percept*,  $t$ ))

*action* := ASK( $KB$ , MAKE-ACTION-QUERY( $t$ ))

TELL( $KB$ , MAKE-ACTION-SENTENCE(*action*,  $t$ ))

$t := t+1$

**return** *action*

## A Simple Formal System: Prop. Logic with Hilbert-Calculus

- ▷ **Formulae:** Built from propositional variables:  $P, Q, R, \dots$  and implication:  $\Rightarrow$
- ▷ **Semantics:**  $\mathcal{I}_\varphi(P) = \varphi(P)$  and  $\mathcal{I}_\varphi(\mathbf{A} \Rightarrow \mathbf{B}) = \mathbf{T}$ , iff  $\mathcal{I}_\varphi(\mathbf{A}) = \mathbf{F}$  or  $\mathcal{I}_\varphi(\mathbf{B}) = \mathbf{T}$ .
- ▷ **Definition 10.3.2.** The **Hilbert calculus**  $\mathcal{H}^0$  consists of the **inference rules**:

$$\frac{}{P \Rightarrow Q \Rightarrow P} \text{K} \qquad \frac{}{(P \Rightarrow Q \Rightarrow R) \Rightarrow (P \Rightarrow Q) \Rightarrow P \Rightarrow R} \text{S}$$

$$\frac{\mathbf{A} \Rightarrow \mathbf{B} \quad \mathbf{A}}{\mathbf{B}} \text{MP} \qquad \frac{\mathbf{A}}{[\mathbf{B}/\mathbf{X}](\mathbf{A})} \text{Subst}$$

▷ **Example 10.3.3.** A  $\mathcal{H}^0$  theorem  $C \Rightarrow C$  and its proof

*Proof:* We show that  $\emptyset \vdash_{\mathcal{H}^0} C \Rightarrow C$

1.  $(C \Rightarrow (C \Rightarrow C) \Rightarrow C) \Rightarrow (C \Rightarrow C \Rightarrow C) \Rightarrow C \Rightarrow C$  (S with  $[C/P], [C \Rightarrow C/Q], [C/R]$ )
2.  $C \Rightarrow (C \Rightarrow C) \Rightarrow C$  (K with  $[C/P], [C \Rightarrow C/Q]$ )
3.  $(C \Rightarrow C \Rightarrow C) \Rightarrow C \Rightarrow C$  (MP on P.1 and P.2)
4.  $C \Rightarrow C \Rightarrow C$  (K with  $[C/P], [C/Q]$ )
5.  $C \Rightarrow C$  (MP on P.3 and P.4)

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 331 2024-02-08

This is indeed a very simple **formal system**, but it has all the required parts:

- A **formal language**: expressions built up from variables and implications.
- A **semantics**: given by the obvious interpretation function
- A **calculus**: given by the two **axioms** and the two **inference rules**.

The **calculus** gives us a set of rules with which we can derive new formulae from old ones. The **axioms** are very simple **rules**, they allow us to derive these two formulae in any situation. The proper **inference rules** are slightly more complicated: we read the formulae above the horizontal line as **assumptions** and the (single) formula below as the **conclusion**. An **inference rule** allows us to **derive** the **conclusion**, if we have already **derived** the **assumptions**.

Now, we can use these **inference rules** to perform a **proof** – a sequence of **formulae** that can be **derived** from each other. The representation of the **proof** in the slide is slightly compactified to fit onto the slide: We will make it more explicit here. We first start out by deriving the **formula**

$$(P \Rightarrow Q \Rightarrow R) \Rightarrow (P \Rightarrow Q) \Rightarrow P \Rightarrow R \quad (10.1)$$

which we can always do, since we have an **axiom** for this **formula**, then we apply the **rule Subst**, where **A** is this result, **B** is  $C$ , and  $X$  is the **variable**  $P$  to obtain

$$(C \Rightarrow Q \Rightarrow R) \Rightarrow (C \Rightarrow Q) \Rightarrow C \Rightarrow R \quad (10.2)$$

Next we apply the **rule Subst** to this where **B** is  $C \Rightarrow C$  and  $X$  is the **variable**  $Q$  this time to obtain

$$(C \Rightarrow (C \Rightarrow C) \Rightarrow R) \Rightarrow (C \Rightarrow C \Rightarrow C) \Rightarrow C \Rightarrow R \quad (10.3)$$

And again, we apply the **rule Subst** this time, **B** is  $C$  and  $X$  is the **variable**  $R$  yielding the first **formula** in our **proof** on the slide. To conserve space, we have combined these three steps into one in the slide. The next steps are done in exactly the same way.

In general formulae can be used to represent facts about the world as propositions; they have a semantics that is a mapping of formulae into the real world (propositions are mapped to truth values.) We have seen two relations on formulae: the **entailment relation** and the deduction relation. The first one is defined purely in terms of the semantics, the second one is given by a **calculus**, i.e. purely syntactically. Is there any relation between these relations?

## Soundness and Completeness

▷ **Definition 10.3.4.** Let  $\mathcal{L} := \langle \mathcal{L}, \mathcal{K}, \models \rangle$  be a **logical system**, then we call a **calculus**  $\mathcal{C}$  for  $\mathcal{L}$ ,

- ▷ **sound** (or **correct**), iff  $\mathcal{H} \models A$ , whenever  $\mathcal{H} \vdash_{\mathcal{C}} A$ , and
- ▷ **complete**, iff  $\mathcal{H} \vdash_{\mathcal{C}} A$ , whenever  $\mathcal{H} \models A$ .

▷ **Goal:** Find **calculi**  $C$ , such that  $\vdash_C A$  iff  $\models A$  (provability and validity coincide)

▷ **To TRUTH through PROOF** (CALCULEMUS [Leibniz ~1680])

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG

Michael Kohlhase: Artificial Intelligence 1

2024-02-08

LOW RIGHTS RESERVE

Ideally, both relations would be the same, then the **calculus** would allow us to infer all facts that can be represented in the given formal language and that are true in the real world, and only those. In other words, our representation and inference is faithful to the world.

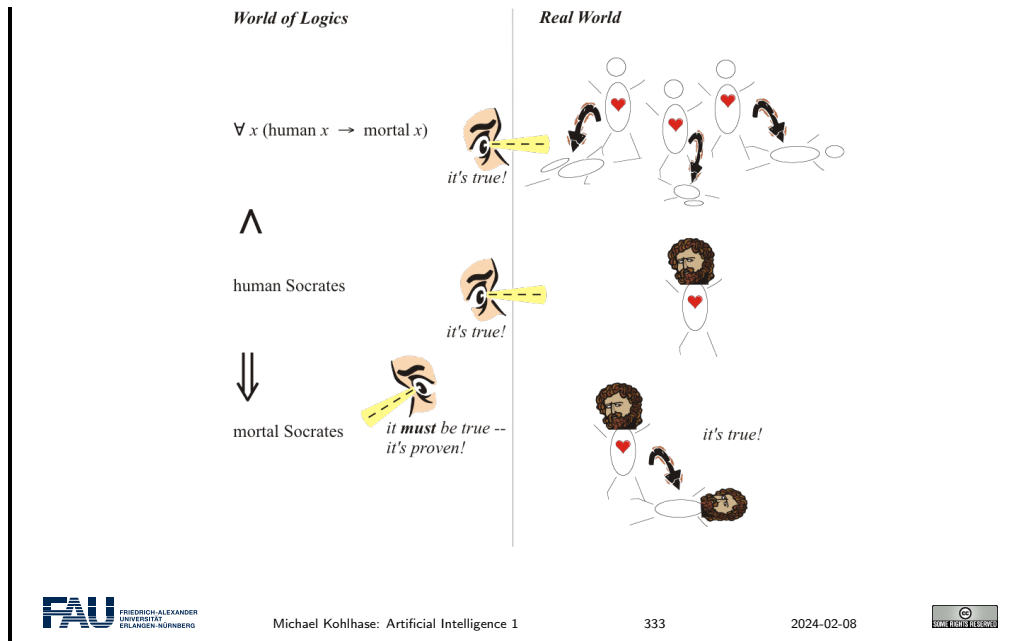

A consequence of this is that we can rely on purely syntactical means to make predictions about the world. **Computers** rely on formal representations of the world; if we want to solve a problem on our **computer**, we first represent it in the **computer** (as **data structures**, which can be seen as a formal language) and do syntactic manipulations on these structures (a form of **calculus**). Now, if the provability relation induced by the **calculus** and the validity relation coincide (this will be quite difficult to establish in general), then the solutions of the program will be **correct**, and we will find all possible ones.

Of course, the logics we have studied so far are very simple, and not able to express interesting facts about the world, but we will study them as a simple example of the fundamental problem of **computer science**: How do the formal representations correlate with the real world. Within the world of logics, one can derive new propositions (the *conclusions*, here: *Socrates is mortal*) from given ones (the *premises*, here: *Every human is mortal* and *Sokrates is human*). Such derivations are *proofs*.

In particular, logics can describe the internal structure of real-life facts; e.g. individual things, actions, properties. A famous example, which is in fact as old as it appears, is illustrated in the slide below.

## The miracle of logics

- ▷ **Purely formal derivations are true in the real world!**

If a **formal system** is **correct**, the conclusions one can prove are true (= hold in the real world) whenever the premises are true. This is a miraculous fact (think about it!)

## 10.4 Propositional Natural Deduction Calculus

**Video Nuggets** covering this section can be found at <https://fau.tv/clip/id/22520> and <https://fau.tv/clip/id/22525>.

We will now introduce the “**natural deduction**” calculus for **propositional logic**. The **calculus** was created in order to model the natural mode of reasoning e.g. in everyday **mathematical** practice. In particular, it was intended as a counter-approach to the well-known Hilbert style calculi, which were mainly used as theoretical devices for studying reasoning in principle, not for modeling particular reasoning styles. We will introduce **natural deduction** in two styles/notation, both were invented by Gerhard Gentzen in the 1930’s and are very much related. The Natural Deduction style (ND) uses “local hypotheses” in proofs for hypothetical reasoning, while the “sequent style” is a rationalized version and extension of the ND calculus that makes certain meta-proofs simpler to push through by making the context of local hypotheses explicit in the notation. The sequent notation also constitutes a more adequate data structure for **implementations**, and user interfaces.

Rather than using a minimal set of **inference rules**, we introduce a **natural deduction calculus** that provides two/three **inference rules** for every **logical constant**, one “**introduction rule**” (an **inference rule** that derives a **formula** with that **logical constant** at the head) and one “**elimination rule**” (an **inference rule** that acts on a **formula** with this head and derives a set of **subformulae**).

### Calculi: Natural Deduction ( $\mathcal{ND}_0$ ; Gentzen [Gen34])

- ▷ **Idea:**  $\mathcal{ND}_0$  tries to mimic human argumentation for **theorem proving**.
- ▷ **Definition 10.4.1.** The **propositional natural deduction calculus**  $\mathcal{ND}_0$  has **inference rules** for the **introduction** and **elimination** of **connectives**:

| Introduction                                       | Elimination                                                  |                                                  | Axiom                                              |
|----------------------------------------------------|--------------------------------------------------------------|--------------------------------------------------|----------------------------------------------------|
| $\frac{A \ B}{A \wedge B} \mathcal{ND}_0 \wedge I$ | $\frac{A \wedge B}{A} \mathcal{ND}_0 \wedge E_l$             | $\frac{A \wedge B}{B} \mathcal{ND}_0 \wedge E_r$ | $\frac{}{A \vee \neg A} \mathcal{ND}_0 \text{TND}$ |
| $\frac{[A]^1}{B} \mathcal{ND}_0 \Rightarrow I^1$   | $\frac{A \Rightarrow B \ A}{B} \mathcal{ND}_0 \Rightarrow E$ |                                                  |                                                    |

$\Rightarrow I$  proves  $A \Rightarrow B$  by exhibiting a  $\mathcal{ND}_0$  derivation  $\mathcal{D}$  (depicted by the double horizontal lines) of  $B$  from the **local hypothesis**  $A$ ;  $\Rightarrow I$  then **discharges** (get rid of  $A$ , which can only be used in  $\mathcal{D}$ ) the **hypothesis** and **concludes**  $A \Rightarrow B$ . This mode of reasoning is called **hypothetical reasoning**.

▷ **Definition 10.4.2.** Given a set  $\mathcal{H} \subseteq \text{wff}_0(\mathcal{V}_0)$  of **assumptions** and a **conclusion**  $C$ , we write  $\mathcal{H} \vdash_{\mathcal{ND}_0} C$ , iff there is a  $\mathcal{ND}_0$  derivation tree whose **leaves** are in  $\mathcal{H}$ .

▷ **Note:**  $\mathcal{ND}_0 \text{TND}$  is used only in **classical logic**. (otherwise constructive/intuitionistic)

Michael Kohlhase: Artificial Intelligence 1
334
2024-02-08

The most characteristic rule in the **natural deduction calculus** is the  $\Rightarrow I$  rule and the **hypothetical reasoning** it introduce.  $\Rightarrow I$  corresponds to the **mathematical** way of proving an **implication**  $A \Rightarrow B$ : We assume that  $A$  is true and show  $B$  from this **local hypothesis**. When we can do this we **discharge** the assumption and conclude  $A \Rightarrow B$ .

Note that the local hypothesis is **discharged** by the rule  $\Rightarrow I$ , i.e. it cannot be used in any other part of the proof. As the  $\Rightarrow I$  rules may be nested, we decorate both the rule and the corresponding assumption with a marker (here the number 1).

Let us now consider an example of **hypothetical reasoning** in action.

### Natural Deduction: Examples

▷ **Example 10.4.3 (Inference with Local Hypotheses).**

|                                                                                                                                                                                                                                                |                                                                                                                                                                                                        |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\frac{\frac{[A \wedge B]^1}{B} \mathcal{ND}_0 \wedge E_r \quad \frac{[A \wedge B]^1}{A} \mathcal{ND}_0 \wedge E_l}{B \wedge A} \mathcal{ND}_0 \wedge I$ $\frac{B \wedge A}{A \wedge B \Rightarrow B \wedge A} \mathcal{ND}_0 \Rightarrow I^1$ | $\frac{[A]^1}{[B]^2} \mathcal{ND}_0 \Rightarrow I^2$ $\frac{A}{B \Rightarrow A} \mathcal{ND}_0 \Rightarrow I^1$ $\frac{B \Rightarrow A}{A \Rightarrow B \Rightarrow A} \mathcal{ND}_0 \Rightarrow I^1$ |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Michael Kohlhase: Artificial Intelligence 1
335
2024-02-08

Here we see **hypothetical reasoning** with **local hypotheses** at work. In the left example, we assume the formula  $A \wedge B$  and can use it in the proof until it is **discharged** by the rule  $\mathcal{ND}_0 \wedge E_l$  on the bottom – therefore we decorate the hypothesis and the rule by corresponding numbers (here the label “1”). Note the **assumption**  $A \wedge B$  is *local to the proof fragment* delineated by the corresponding **hypothesis** and the **discharging rule**, i.e. even if this proof is only a fragment of a larger proof, then we cannot use its **hypothesis** anywhere else.

Note also that we can use as many copies of the local hypothesis as we need; they are all discharged at the same time.

In the right example we see that **local hypotheses** can be nested as long as they are kept local. In particular, we may not use the hypothesis **B** after the  $\mathcal{ND}_0 \Rightarrow I^2$ , e.g. to continue with a  $\mathcal{ND}_0 \Rightarrow E$ .

One of the nice things about the natural deduction calculus is that the deduction theorem is almost trivial to prove. In a sense, the triviality of the deduction theorem is the central idea of the calculus and the feature that makes it so natural.

### A Deduction Theorem for $\mathcal{ND}_0$

- ▷ **Theorem 10.4.4.**  $\mathcal{H}, A \vdash_{\mathcal{ND}_0} B$ , iff  $\mathcal{H} \vdash_{\mathcal{ND}_0} A \Rightarrow B$ .
- ▷ *Proof:* We show the two directions separately
  1. If  $\mathcal{H}, A \vdash_{\mathcal{ND}_0} B$ , then  $\mathcal{H} \vdash_{\mathcal{ND}_0} A \Rightarrow B$  by  $\mathcal{ND}_0 \Rightarrow I$ , and
  2. If  $\mathcal{H} \vdash_{\mathcal{ND}_0} A \Rightarrow B$ , then  $\mathcal{H}, A \vdash_{\mathcal{ND}_0} B$  by weakening and  $\mathcal{H}, A \vdash_{\mathcal{ND}_0} B$  by  $\mathcal{ND}_0 \Rightarrow E$ .

Michael Kohlhase: Artificial Intelligence 1
336
2024-02-08

Another characteristic of the natural deduction calculus is that it has inference rules (introduction and elimination rules) for all **connectives**. So we extend the set of rules from Definition 10.4.1 for disjunction, negation and falsity.

### More Rules for Natural Deduction

- ▷ **Note:**  $\mathcal{ND}_0$  does not try to be minimal, but comfortable to work in!
- ▷ **Definition 10.4.5.**  $\mathcal{ND}_0$  has the following additional **inference rules** for the remaining **connectives**.

$$\frac{A}{A \vee B} \mathcal{ND}_0 \vee I_l \quad \frac{B}{A \vee B} \mathcal{ND}_0 \vee I_r \quad \frac{\begin{array}{c} [A]^1 \quad [B]^1 \\ A \vee B \\ \vdots \\ C \end{array}}{C} \mathcal{ND}_0 \vee E^1$$

$$\frac{\begin{array}{c} [A]^1 \quad [A]^1 \\ \vdots \\ C \end{array}}{\neg A} \mathcal{ND}_0 \neg I^1 \quad \frac{\neg \neg A}{A} \mathcal{ND}_0 \neg E$$

$$\frac{\neg A \quad A}{F} \mathcal{ND}_0 FI \quad \frac{F}{A} \mathcal{ND}_0 FE$$

- ▷ **Again:**  $\mathcal{ND}_0 \neg E$  is used only in **classical logic** (otherwise constructive/intuitionistic)

Michael Kohlhase: Artificial Intelligence 1
337
2024-02-08

## Natural Deduction in Sequent Calculus Formulation

- ▷ **Idea:** Represent **hypotheses** explicitly. (lift calculus to judgments)
- ▷ **Definition 10.4.6.** A **judgment** is a meta statement about the provability of **propositions**.
- ▷ **Definition 10.4.7.** A **sequent** is a **judgment** of the form  $\mathcal{H} \vdash A$  about the provability of the **formula**  $A$  from the set  $\mathcal{H}$  of **hypotheses**. We write  $\vdash A$  for  $\emptyset \vdash A$ .
- ▷ **Idea:** Reformulate  $\mathcal{ND}_0$  **inference rules** so that they act on **sequents**.
- ▷ **Example 10.4.8.** We give the **sequent style version** of Example 10.4.3:

$$\begin{array}{c}
 \frac{}{A \wedge B \vdash A \wedge B} \mathcal{ND}_\vdash^0 Ax \qquad \frac{}{A \wedge B \vdash A \wedge B} \mathcal{ND}_\vdash^0 Ax \\
 \frac{}{A \wedge B \vdash B} \mathcal{ND}_\vdash^0 \wedge E_r \qquad \frac{}{A \wedge B \vdash A} \mathcal{ND}_\vdash^0 \wedge E_l \qquad \frac{}{A, B \vdash A} \mathcal{ND}_\vdash^0 Ax \\
 \frac{}{A \wedge B \vdash B \wedge A} \mathcal{ND}_\vdash^0 \wedge I \qquad \frac{}{A \vdash B \Rightarrow A} \mathcal{ND}_\vdash^0 \Rightarrow I \\
 \frac{}{\vdash A \wedge B \Rightarrow B \wedge A} \mathcal{ND}_\vdash^0 \Rightarrow I \qquad \frac{}{\vdash A \Rightarrow B \Rightarrow A} \mathcal{ND}_\vdash^0 \Rightarrow I
 \end{array}$$

- ▷ **Note:** Even though the antecedent of a **sequent** is written like a **sequences**, it is actually a **set**. In particular, we can **permute** and **duplicate members** at will.

## Sequent-Style Rules for Natural Deduction

- ▷ **Definition 10.4.9.** The following **inference rules** make up the **propositional sequent style natural deduction calculus**  $\mathcal{ND}_\vdash^0$ :

$$\begin{array}{c}
 \frac{}{\Gamma, A \vdash A} \mathcal{ND}_\vdash^0 Ax \qquad \frac{\Gamma \vdash B}{\Gamma, A \vdash B} \mathcal{ND}_\vdash^0 \text{weaken} \qquad \frac{}{\Gamma \vdash A \vee \neg A} \mathcal{ND}_\vdash^0 \text{TND} \\
 \frac{\Gamma \vdash A \quad \Gamma \vdash B}{\Gamma \vdash A \wedge B} \mathcal{ND}_\vdash^0 \wedge I \qquad \frac{\Gamma \vdash A \wedge B}{\Gamma \vdash A} \mathcal{ND}_\vdash^0 \wedge E_l \qquad \frac{\Gamma \vdash A \wedge B}{\Gamma \vdash B} \mathcal{ND}_\vdash^0 \wedge E_r \\
 \frac{\Gamma \vdash A}{\Gamma \vdash A \vee B} \mathcal{ND}_\vdash^0 \vee I_l \qquad \frac{\Gamma \vdash B}{\Gamma \vdash A \vee B} \mathcal{ND}_\vdash^0 \vee I_r \qquad \frac{\Gamma \vdash A \vee B \quad \Gamma, A \vdash C \quad \Gamma, B \vdash C}{\Gamma \vdash C} \mathcal{ND}_\vdash^0 \vee E \\
 \frac{\Gamma, A \vdash B}{\Gamma \vdash A \Rightarrow B} \mathcal{ND}_\vdash^0 \Rightarrow I \qquad \frac{\Gamma \vdash A \Rightarrow B \quad \Gamma \vdash A}{\Gamma \vdash B} \mathcal{ND}_\vdash^0 \Rightarrow E \\
 \frac{\Gamma, A \vdash F}{\Gamma \vdash \neg A} \mathcal{ND}_\vdash^0 \neg I \qquad \frac{\Gamma \vdash \neg \neg A}{\Gamma \vdash A} \mathcal{ND}_\vdash^0 \neg E \\
 \mathcal{ND}_\vdash^0 FI \quad \frac{\Gamma \vdash \neg A \quad \Gamma \vdash A}{\Gamma \vdash F} \qquad \mathcal{ND}_\vdash^0 FE \quad \frac{\Gamma \vdash F}{\Gamma \vdash A}
 \end{array}$$

### Linearized Notation for (Sequent-Style) ND Proofs

▷ Linearized notation for sequent-style ND proofs

$$\begin{array}{l}
 1. \mathcal{H}_1 \vdash A_1 \quad (\mathcal{J}_1) \\
 2. \mathcal{H}_2 \vdash A_2 \quad (\mathcal{J}_2) \\
 3. \mathcal{H}_3 \vdash A_3 \quad (\mathcal{J}_3 1, 2)
 \end{array}
 \quad \text{corresponds to} \quad
 \frac{\mathcal{H}_1 \vdash A_1 \quad \mathcal{H}_2 \vdash A_2}{\mathcal{H}_3 \vdash A_3} \mathcal{R}$$

▷ **Example 10.4.10.** We show a linearized version of the  $\mathcal{ND}_0$  examples Example 10.4.8

$$\frac{\frac{\frac{\frac{}{\mathbf{A} \wedge \mathbf{B} \vdash \mathbf{A} \wedge \mathbf{B}}{\mathcal{ND}_\vdash^0 \wedge E_r} \mathbf{A} \wedge \mathbf{B} \vdash \mathbf{A}}{\mathcal{ND}_\vdash^0 \wedge E_l} \mathbf{A} \wedge \mathbf{B} \vdash \mathbf{B}}{\mathcal{ND}_\vdash^0 \wedge I} \mathbf{A} \wedge \mathbf{B} \vdash \mathbf{A} \wedge \mathbf{B}}{\mathcal{ND}_\vdash^0 \Rightarrow I} \mathbf{A} \wedge \mathbf{B} \Rightarrow \mathbf{B} \wedge \mathbf{A}}$$

$$\frac{\frac{\frac{}{\mathbf{A}, \mathbf{B} \vdash \mathbf{A}}{\mathcal{ND}_\vdash^0 \Rightarrow I} \mathbf{A} \vdash \mathbf{B} \Rightarrow \mathbf{A}}{\mathcal{ND}_\vdash^0 \Rightarrow I} \vdash \mathbf{A} \Rightarrow \mathbf{B} \Rightarrow \mathbf{A}}$$

Each row in the table represents one inference step in the proof. It consists of line number (for referencing), a formula for the asserted property, a justification via a ND (and the rows this one is derived from), and finally a list of row numbers of proof steps that are local hypotheses in effect for the current row.

## 10.5 Predicate Logic Without Quantifiers

In the hair-color example we have seen that we are able to model complex situations in  $\text{PL}^0$ . The trick of using variables with fancy names like  $bla(N)$  is a bit dubious, and we can already imagine that it will be difficult to support programmatically unless we make names like  $bla(N)$  into first class citizens i.e. expressions of the logic language themselves.

### Issues with Propositional Logic

▷ **Awkward to write for humans:** E.g., to model the Wumpus world we had to make a copy of the rules for every cell ...

$$\begin{array}{l}
 R_1 := \neg S_{1,1} \Rightarrow \neg W_{1,1} \wedge \neg W_{1,2} \wedge \neg W_{2,1} \\
 R_2 := \neg S_{2,1} \Rightarrow \neg W_{1,1} \wedge \neg W_{2,1} \wedge \neg W_{2,2} \wedge \neg W_{3,1} \\
 R_3 := \neg S_{1,2} \Rightarrow \neg W_{1,1} \wedge \neg W_{1,2} \wedge \neg W_{2,2} \wedge \neg W_{1,3}
 \end{array}$$

Compared to

*Cell adjacent to Wumpus: Stench (else: None)*

that is not a very nice description language ...

▷ **Can we design a more human-like logic?:** Yep!

- ▷ **Idea:** Introduce explicit representations for
  - ▷ individuals, e.g. the wumpus, the gold, numbers, ...
  - ▷ functions on individuals, e.g. the cell at  $i, j$ , ...
  - ▷ relations between them, e.g. being in a cell, being adjacent, ...

This is essentially the same as  $PL^0$ , so we can reuse the **calculi**. (up next)

## Individuals and their Properties/Relations

- ▷ **Observation:** We want to talk about **individuals** like Stefan, Nicole, and Jochen and their properties, e.g. being blond, or studying AI and relationships, e.g. that *Stefan loves Nicole*.
- ▷ **Idea:** Re-use  $PL^0$ , but replace **propositional variables** with something more expressive! (instead of fancy variable name trick)
- ▷ **Definition 10.5.1.** A **first-order signature**  $\langle \Sigma^f, \Sigma^p \rangle$  consists of
  - ▷  $\Sigma^f := \bigcup_{k \in \mathbb{N}} \Sigma_k^f$  of **function constants**, where members of  $\Sigma_k^f$  denote  $k$ -ary functions on **individuals**,
  - ▷  $\Sigma^p := \bigcup_{k \in \mathbb{N}} \Sigma_k^p$  of **predicate constants**, where members of  $\Sigma_k^p$  denote  $k$ -ary relations among **individuals**,

where  $\Sigma_k^f$  and  $\Sigma_k^p$  are **pairwise disjoint, countable sets of symbols** for each  $k \in \mathbb{N}$ .

- ▷ **Definition 10.5.2.** The formulae of  $PE^q$  are given by the following **grammar**

|                     |       |       |                        |             |
|---------------------|-------|-------|------------------------|-------------|
| function constants  | $f^k$ | $\in$ | $\Sigma_k^f$           |             |
| predicate constants | $p^k$ | $\in$ | $\Sigma_k^p$           |             |
| terms               | $t$   | $::=$ | $f^0$                  | constant    |
|                     |       |       | $f^k(t_1, \dots, t_k)$ | application |
| formulae            | $A$   | $::=$ | $p^k(t_1, \dots, t_k)$ | atomic      |
|                     |       |       | $\neg A$               | negation    |
|                     |       |       | $A_1 \wedge A_2$       | conjunction |

## $PE^q$ Semantics

- ▷ **Definition 10.5.3.** **Domains**  $\mathcal{D}_0 = \{T, F\}$  of **truth values** and  $\mathcal{D}_i \neq \emptyset$  of **individuals**.
- ▷ **Definition 10.5.4.** **Interpretation**  $\mathcal{I}$  assigns values to constants, e.g.
  - ▷  $\mathcal{I}(\neg): \mathcal{D}_0 \rightarrow \mathcal{D}_0; T \mapsto F; F \mapsto T$  and  $\mathcal{I}(\wedge) = \dots$  (as in  $PL^0$ )
  - ▷  $\mathcal{I}: \Sigma_0^f \rightarrow \mathcal{D}_i$  (interpret individual constants as individuals)
  - ▷  $\mathcal{I}: \Sigma_k^f \rightarrow \mathcal{D}_i^k \rightarrow \mathcal{D}_i$  (interpret function constants as functions)

▷  $\mathcal{I}: \Sigma_k^p \rightarrow \mathcal{P}(\mathcal{D}_i^k)$  (interpret predicate constants as relations)

▷ **Definition 10.5.5.** The **value function**  $\mathcal{I}$  assigns values to formulae: (recursively)

▷  $\mathcal{I}(f(\mathbf{A}^1, \dots, \mathbf{A}^k)) := \mathcal{I}(f)(\mathcal{I}(\mathbf{A}^1), \dots, \mathcal{I}(\mathbf{A}^k))$

▷  $\mathcal{I}(p(\mathbf{A}^1, \dots, \mathbf{A}^k)) := \mathbf{T}$ , iff  $\langle \mathcal{I}(\mathbf{A}^1), \dots, \mathcal{I}(\mathbf{A}^k) \rangle \in \mathcal{I}(p)$

▷  $\mathcal{I}(\neg \mathbf{A}) = \mathcal{I}(\neg)(\mathcal{I}(\mathbf{A}))$  and  $\mathcal{I}(\mathbf{A} \wedge \mathbf{B}) = \mathcal{I}(\wedge)(\mathcal{I}(\mathbf{A}), \mathcal{I}(\mathbf{B}))$  (just as in  $\text{PL}^0$ )

▷ **Definition 10.5.6. Model:**  $\mathcal{M} = \langle \mathcal{D}_i, \mathcal{I} \rangle$  varies in  $\mathcal{D}_i$  and  $\mathcal{I}$ .

▷ **Theorem 10.5.7.**  $\text{PE}^q$  is isomorphic to  $\text{PL}^0$  (interpret atoms as prop. variables)

## A Model for $\text{PE}^q$

▷ **Example 10.5.8.** Let  $L := \{a, b, c, d, e, P, Q, R, S\}$ , we set the universe  $\mathcal{D} := \{\clubsuit, \spadesuit, \heartsuit, \diamondsuit\}$ , and specify the interpretation function  $\mathcal{I}$  by setting

▷  $a \mapsto \clubsuit$ ,  $b \mapsto \spadesuit$ ,  $c \mapsto \heartsuit$ ,  $d \mapsto \diamondsuit$ , and  $e \mapsto \diamondsuit$  for constants,

▷  $P \mapsto \{\clubsuit, \spadesuit\}$  and  $Q \mapsto \{\spadesuit, \diamondsuit\}$ , for unary predicate constants.

▷  $R \mapsto \{\langle \heartsuit, \diamondsuit \rangle, \langle \diamondsuit, \heartsuit \rangle\}$ , and  $S \mapsto \{\langle \diamondsuit, \spadesuit \rangle, \langle \spadesuit, \clubsuit \rangle\}$  for binary predicate constants.

▷ **Example 10.5.9 (Computing Meaning in this Model).**

▷  $\mathcal{I}(R(a, b) \wedge P(c)) = \mathbf{T}$ , iff

▷  $\mathcal{I}(R(a, b)) = \mathbf{T}$  and  $\mathcal{I}(P(c)) = \mathbf{T}$ , iff

▷  $\langle \mathcal{I}(a), \mathcal{I}(b) \rangle \in \mathcal{I}(R)$  and  $\mathcal{I}(c) \in \mathcal{I}(P)$ , iff

▷  $\langle \clubsuit, \spadesuit \rangle \in \{\langle \heartsuit, \diamondsuit \rangle, \langle \diamondsuit, \heartsuit \rangle\}$  and  $\heartsuit \in \{\clubsuit, \spadesuit\}$

So,  $\mathcal{I}(R(a, b) \wedge P(c)) = \mathbf{F}$ .

## $\text{PE}^q$ and $\text{PL}^0$ are Isomorphic

▷ **Observation:** For every choice of  $\Sigma$  of signature, the set  $\mathcal{A}_\Sigma$  of atomic  $\text{PE}^q$  formulae is countable, so there is a  $\mathcal{V}_\Sigma \subseteq \mathcal{V}_0$  and a bijection  $\theta_\Sigma: \mathcal{A}_\Sigma \rightarrow \mathcal{V}_\Sigma$ .

$\theta_\Sigma$  can be extended to formulae as  $\text{PE}^q$  and  $\text{PL}^0$  share connectives.

▷ **Lemma 10.5.10.** For every model  $\mathcal{M} = \langle \mathcal{D}_i, \mathcal{I} \rangle$ , there is a variable assignment  $\varphi_{\mathcal{M}}$ , such that  $\mathcal{I}_{\varphi_{\mathcal{M}}}(\mathbf{A}) = \mathcal{I}(\mathbf{A})$ .

▷ *Proof sketch:* We just define  $\varphi_{\mathcal{M}}(X) := \mathcal{I}(\theta_\Sigma^{-1}(X))$

▷ **Lemma 10.5.11.** For every variable assignment  $\psi: \mathcal{V}_\Sigma \rightarrow \{\mathbf{T}, \mathbf{F}\}$  there is a model  $\mathcal{M}^\psi = \langle \mathcal{D}^\psi, \mathcal{I}^\psi \rangle$ , such that  $\mathcal{I}_\psi(\mathbf{A}) = \mathcal{I}^\psi(\mathbf{A})$ .

▷ *Proof sketch:* see next slide

- ▷ **Corollary 10.5.12.**  $\text{PE}^q$  is isomorphic to  $\text{PL}^0$ , i.e. the following diagram commutes:

$$\begin{array}{ccc} \langle \mathcal{D}^\psi, \mathcal{I}^\psi \rangle & \xleftarrow{\psi \mapsto \mathcal{M}^\psi} & \mathcal{V}_\Sigma \rightarrow \{\mathbf{T}, \mathbf{F}\} \\ \mathcal{I}^\psi() \uparrow & & \uparrow \mathcal{I}_{\varphi, \mathcal{M}}() \\ \text{PE}^q(\Sigma) & \xrightarrow{\theta_\Sigma} & \text{PL}^0(\mathcal{A}_\Sigma) \end{array}$$

- ▷ **Note:** This constellation with a language isomorphism and a corresponding model isomorphism (in converse direction) is typical for a logic isomorphism.

## Valuation and Satisfiability

- ▷ **Lemma 10.5.13.** For every variable assignment  $\psi: \mathcal{V}_\Sigma \rightarrow \{\mathbf{T}, \mathbf{F}\}$  there is a model  $\mathcal{M}^\psi = \langle \mathcal{D}^\psi, \mathcal{I}^\psi \rangle$ , such that  $\mathcal{I}_\psi(\mathbf{A}) = \mathcal{I}^\psi(\mathbf{A})$ .

- ▷ *Proof:* We construct  $\mathcal{M}^\psi = \langle \mathcal{D}^\psi, \mathcal{I}^\psi \rangle$  and show that it works as desired.

1. Let  $\mathcal{D}^\psi$  be the set of  $\text{PE}^q$  terms over  $\Sigma$ , and
  - ▷  $\mathcal{I}^\psi(f): \mathcal{D}_i^k \rightarrow \mathcal{D}^k; \langle \mathbf{A}_1, \dots, \mathbf{A}_k \rangle \mapsto f(\mathbf{A}_1, \dots, \mathbf{A}_k)$  for  $f \in \Sigma_k^f$
  - ▷  $\mathcal{I}^\psi(p) := \{ \langle \mathbf{A}_1, \dots, \mathbf{A}_k \rangle \mid \psi(\theta_\psi^{-1} p(\mathbf{A}_1, \dots, \mathbf{A}_k)) = \mathbf{T} \}$  for  $p \in \Sigma^p$ .
2. We show  $\mathcal{I}^\psi(\mathbf{A}) = \mathbf{A}$  for terms  $\mathbf{A}$  by induction on  $\mathbf{A}$ 
  - 2.1. If  $\mathbf{A} = c$ , then  $\mathcal{I}^\psi(\mathbf{A}) = \mathcal{I}^\psi(c) = c = \mathbf{A}$
  - 2.2. If  $\mathbf{A} = f(\mathbf{A}_1, \dots, \mathbf{A}_n)$  then
 
$$\mathcal{I}^\psi(\mathbf{A}) = \mathcal{I}^\psi(f)(\mathcal{I}(\mathbf{A}_1), \dots, \mathcal{I}(\mathbf{A}_n)) = \mathcal{I}^\psi(f)(\mathbf{A}_1, \dots, \mathbf{A}_k) = \mathbf{A}.$$
3. For a  $\text{PE}^q$  formula  $\mathbf{A}$  we show that  $\mathcal{I}^\psi(\mathbf{A}) = \mathcal{I}_\psi(\mathbf{A})$  by induction on  $\mathbf{A}$ .
  - 3.1. If  $\mathbf{A} = p(\mathbf{A}_1, \dots, \mathbf{A}_k)$ , then  $\mathcal{I}^\psi(\mathbf{A}) = \mathcal{I}^\psi(p)(\mathcal{I}(\mathbf{A}_1), \dots, \mathcal{I}(\mathbf{A}_n)) = \mathbf{T}$ , iff  $\langle \mathbf{A}_1, \dots, \mathbf{A}_k \rangle \in \mathcal{I}^\psi(p)$ , iff  $\psi(\theta_\psi^{-1} \mathbf{A}) = \mathbf{T}$ , so  $\mathcal{I}^\psi(\mathbf{A}) = \mathcal{I}_\psi(\mathbf{A})$  as desired.
  - 3.2. If  $\mathbf{A} = \neg \mathbf{B}$ , then  $\mathcal{I}^\psi(\mathbf{A}) = \mathbf{T}$ , iff  $\mathcal{I}^\psi(\mathbf{B}) = \mathbf{F}$ , iff  $\mathcal{I}^\psi(\mathbf{B}) = \mathcal{I}_\psi(\mathbf{B})$ , iff  $\mathcal{I}^\psi(\mathbf{A}) = \mathcal{I}_\psi(\mathbf{A})$ .
  - 3.3. If  $\mathbf{A} = \mathbf{B} \wedge \mathbf{C}$  then we argue similarly
4. Hence  $\mathcal{I}^\psi(\mathbf{A}) = \mathcal{I}_\psi(\mathbf{A})$  for all  $\text{PE}^q$  formulae and we have concluded the proof.

## 10.6 Conclusion

A Video Nugget covering this section can be found at <https://fau.tv/clip/id/25027>.

### Summary

- ▷ Sometimes, it pays off to think before acting.
- ▷ In AI, “thinking” is implemented in terms of reasoning to deduce new knowledge from a knowledge base represented in a suitable logic.

- ▷ Logic prescribes a **syntax** for formulas, as well as a **semantics** prescribing which **interpretations** satisfy them. **A entails B** if all **interpretations** that **satisfy A** also **satisfy B**. **Deduction** is the process of deriving new **entailed formulae**.
- ▷ **Propositional logic** formulas are built from **atomic propositions**, with the **connectives** *and, or, not*.

## Issues with Propositional Logic

- ▷ **Time**: For things that change (e.g., **Wumpus** moving according to certain rules), we need time-indexed propositions (like,  $S_{2,1}^{t=7}$ ) to represent validity over time  $\rightsquigarrow$  further expansion of the rules.
- ▷ **Can we design a more human-like logic?:** Yep
  - ▷ **Predicate logic**: **quantification** of **variables** ranging over **individuals**. (cf. **chapter 14** and **chapter 15**)
  - ▷ ... and a whole zoo of logics much more powerful still.
  - ▷ **Note**: In applications, propositional **CNF** encodings are generated by **computer programs**. This mitigates (but does not remove!) the inconveniences of propositional modeling.

### Suggested Reading:

- *Chapter 7: Logical Agents*, Sections 7.1 – 7.5 [RN09].
  - Sections 7.1 and 7.2 roughly correspond to my “Introduction”, Section 7.3 roughly corresponds to my “Logic (in AI)”, Section 7.4 roughly corresponds to my “Propositional Logic”, Section 7.5 roughly corresponds to my “Resolution” and “Killing a Wumpus”.
  - Overall, the content is quite similar. I have tried to add some additional clarifying illustrations. RN gives many complementary explanations, nice as additional background reading.
  - I would note that RN’s presentation of resolution seems a bit awkward, and Section 7.5 contains some additional material that is imho not interesting (alternate inference rules, forward and backward chaining). **Horn clauses** and unit resolution (also in Section 7.5), on the other hand, are quite relevant.

# Chapter 11

## Machine-Oriented Calculi for Propositional Logic

A **Video Nugget** covering this chapter can be found at <https://fau.tv/clip/id/22531>.

### Automated Deduction as an Agent Inference Procedure

- ▷ **Recall:** Our knowledge of the cave entails a definite **Wumpus** position!(slide 312)
- ▷ **Problem:** That was human reasoning, can we build an **agent function** that does this?
- ▷ **Answer:** As for **constraint networks**, we use **inference**, here **resolution/tableaux**.

 FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 349 2024-02-08 

The following theorem is simple, but will be crucial later on.

### Unsatisfiability Theorem

- ▷ **Theorem 11.0.1 (Unsatisfiability Theorem).**  $\mathcal{H} \models \mathbf{A}$  iff  $\mathcal{H} \cup \{\neg \mathbf{A}\}$  is *unsatisfiable*.
- ▷ *Proof:* We prove both directions separately
  1. " $\Rightarrow$ ": Say  $\mathcal{H} \models \mathbf{A}$ 
    - 1.1. For any  $\varphi$  with  $\varphi \models \mathcal{H}$  we have  $\varphi \models \mathbf{A}$  and thus  $\varphi \not\models \neg \mathbf{A}$ .
    2. " $\Leftarrow$ ": Say  $\mathcal{H} \cup \{\neg \mathbf{A}\}$  is *unsatisfiable*.
      - 2.1. For any  $\varphi$  with  $\varphi \models \mathcal{H}$  we have  $\varphi \not\models \neg \mathbf{A}$  and thus  $\varphi \models \mathbf{A}$ .
- ▷ **Observation 11.0.2.** *Entailment can be tested via satisfiability.*

 FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 350 2024-02-08 

### Test Calculi: A Paradigm for Automating Inference

- ▷ **Definition 11.0.3.** Given a **logical system**  $\mathcal{L}$  and a **conjecture**  $C$ , **theorem proving** consists of finding a **calculus** for  $\mathcal{L}$  and establishing that  $C$  is **valid** in the induced

**formal system:** Given a formal system  $\langle \mathcal{L}, \mathcal{K}, \models, \mathcal{C} \rangle$ , the task of **theorem proving** consists in determining whether  $\mathcal{H} \vdash_{\mathcal{C}} C$  for a **conjecture**  $C \in \mathcal{L}$  and **hypotheses**  $\mathcal{H} \subseteq \mathcal{L}$ .

- ▷ **Definition 11.0.4.** **Automated theorem proving (ATP)** is the **automation** of **theorem proving**: Given a **logical system**  $\mathcal{L} := \langle \mathcal{L}, \mathcal{K}, \models \rangle$ , the task of **automated theorem proving** consists of developing **calculi** for  $\mathcal{L}$  and **programs** – called **(automated) theorem provers** – that given a set  $\mathcal{H} \subseteq \mathcal{L}$  of **hypotheses** and a **conjecture**  $A \in \mathcal{L}$  determine whether  $\mathcal{H} \models A$  (usually by **searching** for  $\mathcal{C}$ -derivations  $\mathcal{H} \vdash_{\mathcal{C}} A$  in a calculus  $\mathcal{C}$ ).
- ▷ **Idea:** ATP with a **calculus**  $\mathcal{C}$  for  $\langle \mathcal{L}, \mathcal{K}, \models \rangle$  induces a **search problem**  $\Pi := \langle \mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$ , where the **states**  $\mathcal{S}$  are sets of **formulae** in  $\mathcal{L}$ , the **actions**  $\mathcal{A}$  are the **inference rules** from  $\mathcal{C}$ , the **initial state**  $\mathcal{I} = \{\mathcal{H}\}$ , and the **goal states** are those with  $A \in \mathcal{S}$ .
- ▷ **Problem:** ATP as a **search problem** does not admit good **heuristics**, since these need to take the **conjecture**  $A$  into account.
- ▷ **Idea:** Turn the search around – using the **unsatisfiability theorem** (Theorem 11.0.1).
- ▷ **Definition 11.0.5.** For a given **conjecture**  $A$  and **hypotheses**  $\mathcal{H}$  a **test calculus**  $\mathcal{T}$  tries to derive  $\mathcal{H}, \bar{A} \vdash_{\mathcal{T}} \perp$  instead of  $\mathcal{H} \vdash A$ , where  $\bar{A}$  is **unsatisfiable** iff  $A$  is **valid** and  $\perp$ , an “obviously” **unsatisfiable formula**.  
A derivation  $\mathcal{H}, \bar{A} \vdash_{\mathcal{T}} \perp$  is called a **refutation** of  $A$  (from  $\mathcal{H}$ , if  $\mathcal{H} \neq \emptyset$ ).
- ▷ **Observation:** A **test calculus**  $\mathcal{C}$  induces a **search problem** where the **initial state** is  $\mathcal{H} \cup \{\neg A\}$  and  $S \in \mathcal{S}$  is a **goal state** iff  $\perp \in S$ . (**proximity of  $\perp$  easier for heuristics**)

## 11.1 Normal Forms

Before we can start, we will need to recap some nomenclature on formulae.

### Recap: Atoms and Literals

- ▷ **Definition 11.1.1.** A **formula** is called **atomic** (or an **atom**) if it does not contain **logical constants**, else it is called **complex**.
- ▷ **Definition 11.1.2.** We call a **pair**  $A^\alpha$  of a **formula** and a **truth value**  $\alpha \in \{T, F\}$  a **labeled formula**. For a **set**  $\Phi$  of **formulae** we use  $\Phi^\alpha := \{A^\alpha \mid A \in \Phi\}$ .
- ▷ **Definition 11.1.3.** A **labeled atom**  $A^\alpha$  is called a (**positive** if  $\alpha = T$ , else **negative**) **literal**.
- ▷ **Intuition:** To **satisfy** a **formula**, we make it “true”. To satisfy a **labeled formula**  $A^\alpha$ , it must have the truth value  $\alpha$ .
- ▷ **Definition 11.1.4.** For a **literal**  $A^\alpha$ , we call the **literal**  $A^\beta$  with  $\alpha \neq \beta$  the **opposite literal** (or **partner literal**).

The idea about **literals** is that they are **atoms** (the simplest formulae) that carry around their intended truth value.

### Alternative Definition: Literals

- ▷ **Note:** Literals are often defined without recurring to labeled formulae:
- ▷ **Definition 11.1.5.** A literal is an atom  $A$  (positive literal) or negated atom  $\neg A$  (negative literal).  $A$  and  $\neg A$  are opposite literals.
- ▷ **Note:** This notion of literal is equivalent to the labeled formulae-notion of literal, but does not generalize as well to logics with more than two truth values.

### Normal Forms

- ▷ There are two quintessential normal forms for propositional formulae: (there are others as well)
- ▷ **Definition 11.1.6.** A formula is in conjunctive normal form (CNF) if it is a conjunction of disjunctions of literals: i.e. if it is of the form  $\bigwedge_{i=1}^n \bigvee_{j=1}^{m_i} l_{ij}$
- ▷ **Definition 11.1.7.** A formula is in disjunctive normal form (DNF) if it is a disjunction of conjunctions of literals: i.e. if it is of the form  $\bigvee_{i=1}^n \bigwedge_{j=1}^{m_i} l_{ij}$
- ▷ **Observation 11.1.8.** Every formula has equivalent formulae in CNF and DNF.

Video Nuggets covering this chapter can be found at <https://fau.tv/clip/id/23705> and <https://fau.tv/clip/id/23708>.

## 11.2 Analytical Tableaux

### Test Calculi: Tableaux and Model Generation

- ▷ **Idea:** A tableau calculus is a test calculus that
  - ▷ analyzes a labeled formulae in a tree to determine satisfiability,
  - ▷ its branches correspond to valuations ( $\rightsquigarrow$  models).
- ▷ **Example 11.2.1.** Tableau calculi try to construct models for labeled formulae:

| Tableau refutation (Validity)                                                                                                             | Model generation (Satisfiability)                                                                                                                                                |
|-------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\models P \wedge Q \Rightarrow Q \wedge P$                                                                                               | $\models P \wedge (Q \vee \neg R) \wedge \neg Q$                                                                                                                                 |
| $(P \wedge Q \Rightarrow Q \wedge P)^F$<br>$(P \wedge Q)^T$<br>$(Q \wedge P)^F$<br>$P^T$<br>$Q^T$<br>$P^F \mid Q^F$<br>$\perp \mid \perp$ | $(P \wedge (Q \vee \neg R) \wedge \neg Q)^T$<br>$(P \wedge (Q \vee \neg R))^T$<br>$\neg Q^T$<br>$Q^F$<br>$P^T$<br>$(Q \vee \neg R)^T$<br>$Q^T \mid \neg R^T$<br>$\perp \mid R^F$ |
| No Model                                                                                                                                  | Herbrand Model $\{P^T, Q^F, R^F\}$<br>$\varphi := \{P \mapsto T, Q \mapsto F, R \mapsto F\}$                                                                                     |

▷ **Idea:** Open branches in saturated tableaux yield models.  
 ▷ **Algorithm:** Fully expand all possible tableaux, (no rule can be applied)  
     ▷ Satisfiable, iff there are open branches (correspond to models)

FRIEDRICH-ALEXANDER  
UNIVERSITÄT  
ERLANGEN-NÜRNBERG

Michael Kohlhase: Artificial Intelligence 1

2024-02-08

Tableau calculi develop a formula in a tree-shaped arrangement that represents a case analysis on when a formula can be made true (or false). Therefore the formulae are decorated with exponents that hold the intended truth value.

On the left we have a **refutation tableau** that analyzes a negated formula (it is decorated with the intended truth value **F**). Both **branches** contain an elementary contradiction  $\perp$ .

On the right we have a **model generation tableau**, which analyzes a positive formula (it is decorated with the intended truth value **T**). This **tableau** uses the same rules as the refutation **tableau**, but makes a case analysis of when this formula can be satisfied. In this case we have a **closed branch** and an **open** one. The latter corresponds a model.

Now that we have seen the examples, we can write down the tableau rules formally.

### Analytical Tableaux (Formal Treatment of $\mathcal{T}_0$ )

▷ **Idea:** A test calculus where
 

- ▷ A **labeled formula** is analyzed in a **tree** to determine **satisfiability**,
- ▷ **branches** correspond to valuations (models)

▷ **Definition 11.2.2.** The **propositional tableau calculus**  $\mathcal{T}_0$  has two **inference rules** per **connective** (one for each possible label)

$$\frac{(A \wedge B)^T}{A^T \mid B^T} \mathcal{T}_0 \wedge \quad \frac{(A \wedge B)^F}{A^F \mid B^F} \mathcal{T}_0 \vee \quad \frac{\neg A^T}{A^F} \mathcal{T}_0 \neg^T \quad \frac{\neg A^F}{A^T} \mathcal{T}_0 \neg^F \quad \frac{A^\alpha \mid A^\beta \quad \alpha \neq \beta}{\perp} \mathcal{T}_0 \perp$$

Use rules exhaustively as long as they contribute new material ( $\rightsquigarrow$  **termination**)

▷ **Definition 11.2.3.** We call any **tree** ( $\mid$  introduces **branches**) produced by the  $\mathcal{T}_0$  **inference rules** from a set  $\Phi$  of **labeled formulae** a **tableau** for  $\Phi$ .

▷ **Definition 11.2.4.** Call a **tableau saturated**, iff no **rule** adds new material and a **branch closed**, iff it ends in  $\perp$ , else **open**. A **tableau is closed**, iff all of its **branches** are.

These **inference rules** act on **tableaux** have to be read as follows: if the formulae over the line appear in a **tableau branch**, then the **branch** can be extended by the formulae or **branches** below the line. There are two rules for each primary **connective**, and a **branch** closing rule that adds the special symbol  $\perp$  (for unsatisfiability) to a **branch**.

We use the **tableau rules** with the convention that they are only applied, if they contribute new material to the **branch**. This ensures termination of the tableau procedure for **propositional logic** (every rule eliminates one primary **connective**).

**Definition 11.2.5.** We will call a **closed tableau** with the **labeled formula**  $\mathbf{A}^\alpha$  at the **root** a **tableau refutation** for  $\mathcal{A}^\alpha$ .

The **saturated tableau** represents a full case analysis of what is necessary to give  $\mathbf{A}$  the truth value  $\alpha$ ; since all **branches** are **closed** (contain contradictions) this is impossible.

### Analytical Tableaux ( $\mathcal{T}_0$ continued)

▷ **Definition 11.2.6 ( $\mathcal{T}_0$ -Theorem/Derivability).**  $\mathbf{A}$  is a  $\mathcal{T}_0$ -**theorem** ( $\vdash_{\mathcal{T}_0} \mathbf{A}$ ), iff there is a **closed tableau** with  $\mathbf{A}^F$  at the **root**.

$\Phi \subseteq \text{wff}_0(\mathcal{V}_0)$  **derives**  $\mathbf{A}$  in  $\mathcal{T}_0$  ( $\Phi \vdash_{\mathcal{T}_0} \mathbf{A}$ ), iff there is a **closed tableau** starting with  $\mathbf{A}^F$  and  $\Phi^T$ . The **tableau** with only a **branch** of  $\mathbf{A}^F$  and  $\Phi^T$  is called **initial** for  $\Phi \vdash_{\mathcal{T}_0} \mathbf{A}$ .

**Definition 11.2.7.** We will call a **tableau refutation** for  $\mathbf{A}^F$  a **tableau proof** for  $\mathbf{A}$ , since it refutes the possibility of finding a model where  $\mathbf{A}$  evaluates to  $F$ . Thus  $\mathbf{A}$  must evaluate to  $T$  in all models, which is just our definition of validity.

Thus the tableau procedure can be used as a calculus for **propositional logic**. In contrast to the propositional Hilbert calculus it does not prove a theorem  $\mathbf{A}$  by deriving it from a set of axioms, but it proves it by refuting its negation. Such calculi are called **negative** or **test calculi**. Generally negative calculi have computational advantages over positive ones, since they have a built-in sense of direction.

We have rules for all the necessary **connectives** (we restrict ourselves to  $\wedge$  and  $\neg$ , since the others can be expressed in terms of these two via the propositional identities above. For instance, we can write  $\mathbf{A} \vee \mathbf{B}$  as  $\neg(\neg\mathbf{A} \wedge \neg\mathbf{B})$ , and  $\mathbf{A} \Rightarrow \mathbf{B}$  as  $\neg\mathbf{A} \vee \mathbf{B}, \dots$ )

We now look at a formulation of **propositional logic** with fancy variable names. Note that **loves(mary, bill)** is just a variable name like  $P$  or  $X$ , which we have used earlier.

### A Valid Real-World Example

▷ **Example 11.2.8.** *If Mary loves Bill and John loves Mary, then John loves Mary*

$$\begin{array}{c}
 (\text{loves}(\text{mary}, \text{bill}) \wedge \text{loves}(\text{john}, \text{mary}) \Rightarrow \text{loves}(\text{john}, \text{mary}))^F \\
 \neg(\neg\neg(\text{loves}(\text{mary}, \text{bill}) \wedge \text{loves}(\text{john}, \text{mary})) \wedge \neg\text{loves}(\text{john}, \text{mary}))^F \\
 (\neg\neg(\text{loves}(\text{mary}, \text{bill}) \wedge \text{loves}(\text{john}, \text{mary})) \wedge \neg\text{loves}(\text{john}, \text{mary}))^T \\
 \neg\neg(\text{loves}(\text{mary}, \text{bill}) \wedge \text{loves}(\text{john}, \text{mary}))^T \\
 \neg(\text{loves}(\text{mary}, \text{bill}) \wedge \text{loves}(\text{john}, \text{mary}))^F \\
 (\text{loves}(\text{mary}, \text{bill}) \wedge \text{loves}(\text{john}, \text{mary}))^T \\
 \neg\text{loves}(\text{john}, \text{mary})^T \\
 \text{loves}(\text{mary}, \text{bill})^T \\
 \text{loves}(\text{john}, \text{mary})^T \\
 \text{loves}(\text{john}, \text{mary})^F \\
 \perp
 \end{array}$$

This is a **closed tableau**, so the  $\text{loves}(\text{mary}, \text{bill}) \wedge \text{loves}(\text{john}, \text{mary}) \Rightarrow \text{loves}(\text{john}, \text{mary})$  is a  $\mathcal{T}_0$ -theorem.

As we will see,  $\mathcal{T}_0$  is **sound** and **complete**, so

$$\text{loves}(\text{mary}, \text{bill}) \wedge \text{loves}(\text{john}, \text{mary}) \Rightarrow \text{loves}(\text{john}, \text{mary})$$

is **valid**.

We could have used the unsatisfiability theorem (Theorem 11.0.1) here to show that *If Mary loves Bill and John loves Mary entails John loves Mary*. But there is a better way to show **entailment**: we directly use derivability in  $\mathcal{T}_0$ .

### Deriving Entailment in $\mathcal{T}_0$

▷ **Example 11.2.9.** *Mary loves Bill and John loves Mary together entail that John loves Mary*

$$\begin{array}{c}
 \text{loves}(\text{mary}, \text{bill})^T \\
 \text{loves}(\text{john}, \text{mary})^T \\
 \text{loves}(\text{john}, \text{mary})^F \\
 \perp
 \end{array}$$

This is a **closed tableau**, so  $\{\text{loves}(\text{mary}, \text{bill}), \text{loves}(\text{john}, \text{mary})\} \vdash_{\mathcal{T}_0} \text{loves}(\text{john}, \text{mary})$ .

Again, as  $\mathcal{T}_0$  is **sound** and **complete** we have

$$\{\text{loves}(\text{mary}, \text{bill}), \text{loves}(\text{john}, \text{mary})\} \models \text{loves}(\text{john}, \text{mary})$$

**Note:** We can also use the tableau calculus to try and show **entailment** (and fail). The nice thing is that the failed proof, we can see what went wrong.

### A Falsifiable Real-World Example

▷ **Example 11.2.10.** \* *If Mary loves Bill or John loves Mary, then John loves Mary*

Try proving the implication (this fails)

$$\begin{array}{l}
 (\text{loves}(\text{mary}, \text{bill}) \vee \text{loves}(\text{john}, \text{mary})) \Rightarrow \text{loves}(\text{john}, \text{mary})^F \\
 \neg(\neg\neg(\text{loves}(\text{mary}, \text{bill}) \vee \text{loves}(\text{john}, \text{mary})) \wedge \neg\text{loves}(\text{john}, \text{mary}))^F \\
 (\neg\neg(\text{loves}(\text{mary}, \text{bill}) \vee \text{loves}(\text{john}, \text{mary})) \wedge \neg\text{loves}(\text{john}, \text{mary}))^T \\
 \quad \neg\text{loves}(\text{john}, \text{mary})^T \\
 \quad \text{loves}(\text{john}, \text{mary})^F \\
 \neg\neg(\text{loves}(\text{mary}, \text{bill}) \vee \text{loves}(\text{john}, \text{mary}))^T \\
 \neg(\text{loves}(\text{mary}, \text{bill}) \vee \text{loves}(\text{john}, \text{mary}))^F \\
 (\text{loves}(\text{mary}, \text{bill}) \vee \text{loves}(\text{john}, \text{mary}))^T \\
 \text{loves}(\text{mary}, \text{bill})^T \quad | \quad \text{loves}(\text{john}, \text{mary})^T \\
 \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \perp
 \end{array}$$

Indeed we can make  $\mathcal{I}_\varphi(\text{loves}(\text{mary}, \text{bill})) = \text{T}$  but  $\mathcal{I}_\varphi(\text{loves}(\text{john}, \text{mary})) = \text{F}$ .

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 360 2024-02-08

Obviously, the tableau above is *saturated*, but not *closed*, so it is not a tableau proof for our initial *entailment* conjecture. We have marked the *literal* on the *open branch* green, since they allow us to read of the conditions of the situation, in which the *entailment* fails to hold. As we intuitively argued above, this is the situation, where *Mary loves Bill*. In particular, the *open branch* gives us a variable assignment (marked in green) that satisfies the initial formula. In this case, *Mary loves Bill*, which is a situation, where the *entailment* fails.

Again, the derivability version is much simpler:

Testing for Entailment in  $\mathcal{T}_0$

▷ **Example 11.2.11.** Does *Mary loves Bill or John loves Mary* entail that *John loves Mary*?

$$\begin{array}{l}
 (\text{loves}(\text{mary}, \text{bill}) \vee \text{loves}(\text{john}, \text{mary}))^T \\
 \quad \text{loves}(\text{john}, \text{mary})^F \\
 \text{loves}(\text{mary}, \text{bill})^T \quad | \quad \text{loves}(\text{john}, \text{mary})^T \\
 \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \perp
 \end{array}$$

This *saturated tableau* has an *open branch* that shows that the *interpretation* with  $\mathcal{I}_\varphi(\text{loves}(\text{mary}, \text{bill})) = \text{T}$  but  $\mathcal{I}_\varphi(\text{loves}(\text{john}, \text{mary})) = \text{F}$  falsifies the derivability/*entailment* conjecture.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 361 2024-02-08

We have seen in the examples above that while it is possible to get by with only the *connectives*  $\vee$  and  $\neg$ , it is a bit unnatural and tedious, since we need to eliminate the other *connectives* first. In this chapter, we will make the *calculus* less frugal by adding *rules* for the other *connectives*, without losing the advantage of dealing with a small *calculus*, which is good making statements about the *calculus* itself.

## 11.3 Practical Enhancements for Tableaux

The main idea here is to add the new rules as *derivable inference rules*, i.e. rules that only abbreviate *derivations* in the original *calculus*. Generally, adding *derivable inference rules* does not change the *derivation relation* of the *calculus*, and is therefore a safe thing to do. In particular, we will add the following rules to our *tableau calculus*.

We will convince ourselves that the first rule is *derivable*, and leave the other ones as an exercise.

### Derived Rules of Inference

▷ **Definition 11.3.1.** An inference rule  $\frac{A_1 \cdots A_n}{C}$  is called *derivable* (or a *derived rule*) in a calculus  $\mathcal{C}$ , if there is a  $\mathcal{C}$  derivation  $A_1, \dots, A_n \vdash_{\mathcal{C}} C$ .

▷ **Definition 11.3.2.** We have the following *derivable inference rules* in  $\mathcal{T}_0$ :

|                                            |                                            |                   |
|--------------------------------------------|--------------------------------------------|-------------------|
| $\frac{(A \Rightarrow B)^T}{A^F \mid B^T}$ | $\frac{(A \Rightarrow B)^F}{A^T \mid B^F}$ | $\frac{A^T}{B^T}$ |
|--------------------------------------------|--------------------------------------------|-------------------|

|                                     |                                     |                                                                |                                                                |
|-------------------------------------|-------------------------------------|----------------------------------------------------------------|----------------------------------------------------------------|
| $\frac{(A \vee B)^T}{A^T \mid B^T}$ | $\frac{(A \vee B)^F}{A^F \mid B^F}$ | $\frac{A \Leftrightarrow B^T}{A^T \mid B^T \mid A^F \mid B^F}$ | $\frac{A \Leftrightarrow B^F}{A^T \mid B^F \mid A^F \mid B^T}$ |
|-------------------------------------|-------------------------------------|----------------------------------------------------------------|----------------------------------------------------------------|

|                            |                                |                     |                                    |
|----------------------------|--------------------------------|---------------------|------------------------------------|
| $A^T$                      | $(A \Rightarrow B)^T$          | $(\neg A \vee B)^T$ | $\neg(\neg\neg A \wedge \neg B)^T$ |
| $(\neg A \wedge \neg B)^F$ | $(\neg\neg A \wedge \neg B)^F$ | $\neg\neg A^F$      | $\neg B^F$                         |
| $A^F$                      | $\perp$                        |                     |                                    |

Michael Kohlhase: Artificial Intelligence 1

2024-02-08

With these *derived rules*, theorem proving becomes quite *efficient*. With these rules, the *tableau* (Example 11.2.8) would have the following simpler form:

### Tableaux with derived Rules (example)

**Example 11.3.3.**

$$\begin{array}{c}
 (\text{loves}(\text{mary}, \text{bill}) \wedge \text{loves}(\text{john}, \text{mary}) \Rightarrow \text{loves}(\text{john}, \text{mary}))^F \\
 (\text{loves}(\text{mary}, \text{bill}) \wedge \text{loves}(\text{john}, \text{mary}))^T \\
 \text{loves}(\text{john}, \text{mary})^F \\
 \text{loves}(\text{mary}, \text{bill})^T \\
 \text{loves}(\text{john}, \text{mary})^T \\
 \perp
 \end{array}$$

## 11.4 Soundness and Termination of Tableaux

As always we need to convince ourselves that the *calculus* is *sound*, otherwise, *tableau proofs* do not guarantee *validity*, which we are after. Since we are now in a *refutation* setting we cannot just show that the *inference rules* preserve *validity*: we care about *unsatisfiability* (which is the dual notion to *validity*), as we want to show the *initial labeled formula* to be *unsatisfiable*. Before we can do this, we have to ask ourselves, what it means to be (un)-satisfiable for a *labeled formula* or a *tableau*.

### Soundness (Tableau)

▷ **Idea:** A *test calculus* is *refutation sound*, iff its *inference rules* preserve *satisfiability* and the *goal formulae* are *unsatisfiable*.

- ▷ **Definition 11.4.1.** A labeled formula  $\mathbf{A}^\alpha$  is **valid under**  $\varphi$ , iff  $\mathcal{I}_\varphi(\mathbf{A}) = \alpha$ .
- ▷ **Definition 11.4.2.** A tableau  $\mathcal{T}$  is **satisfiable**, iff there is a **satisfiable branch**  $\mathcal{P}$  in  $\mathcal{T}$ , i.e. if the set of formulae on  $\mathcal{P}$  is **satisfiable**.
- ▷ **Lemma 11.4.3.**  $\mathcal{T}_0$  rules transform **satisfiable tableaux** into **satisfiable ones**.
- ▷ **Theorem 11.4.4 (Soundness).**  $\mathcal{T}_0$  is **sound**, i.e.  $\Phi \subseteq \text{wff}_0(\mathcal{V}_0)$  **valid**, if there is a **closed tableau**  $\mathcal{T}$  for  $\Phi^F$ .
- ▷ **Proof:** by contradiction
  1. Suppose  $\Phi$  is **falsifiable**  $\hat{=}$  not **valid**.
  2. Then the **initial tableau** is **satisfiable**, ( $\Phi^F$  satisfiable)
  3. so  $\mathcal{T}$  is **satisfiable**, by Lemma 11.4.3.
  4. Thus there is a **satisfiable branch** (by definition)
  5. but all **branches** are **closed** ( $\mathcal{T}$  closed)
- ▷ **Theorem 11.4.5 (Completeness).**  $\mathcal{T}_0$  is **complete**, i.e. if  $\Phi \subseteq \text{wff}_0(\mathcal{V}_0)$  is **valid**, then there is a **closed tableau**  $\mathcal{T}$  for  $\Phi^F$ .

*Proof sketch:* Proof difficult/interesting; see Corollary A.2.2

Thus we only have to prove Lemma 11.4.3, this is relatively easy to do. For instance for the first rule: if we have a **tableau** that contains  $(\mathbf{A} \wedge \mathbf{B})^T$  and is **satisfiable**, then it must have a **satisfiable branch**. If  $(\mathbf{A} \wedge \mathbf{B})^T$  is not on this **branch**, the tableau extension will not change **satisfiability**, so we can assume that it is on the **satisfiable branch** and thus  $\mathcal{I}_\varphi(\mathbf{A} \wedge \mathbf{B}) = T$  for some variable assignment  $\varphi$ . Thus  $\mathcal{I}_\varphi(\mathbf{A}) = T$  and  $\mathcal{I}_\varphi(\mathbf{B}) = T$ , so after the extension (which adds the formulae  $\mathbf{A}^T$  and  $\mathbf{B}^T$  to the **branch**), the **branch** is still **satisfiable**. The cases for the other rules are similar.

The next result is a very important one, it shows that there is a procedure (the tableau procedure) that will always **terminate** and answer the question whether a given propositional formula is valid or not. This is very important, since other logics (like the often-studied **first-order logic**) does not enjoy this property.

### ▷ Termination for Tableaux

- ▷ **Lemma 11.4.6.**  $\mathcal{T}_0$  **terminates**, i.e. every  $\mathcal{T}_0$  **tableau** becomes **saturated** after **finitely many rule applications**.
- ▷ **Proof:** By examining the rules wrt. a measure  $\mu$ 
  1. Let us call a **labeled formulae**  $\mathbf{A}^\alpha$  **worked off** in a **tableau**  $\mathcal{T}$ , if a  $\mathcal{T}_0$  rule has already been applied to it.
  2. It is easy to see that applying rules to **worked off formulae** will only add **formulae** that are already present in its **branch**.
  3. Let  $\mu(\mathcal{T})$  be the number of **connectives** in **labeled formulae** in  $\mathcal{T}$  that are not **worked off**.
  4. Then each rule application to a **labeled formula** in  $\mathcal{T}$  that is not **worked off** reduces  $\mu(\mathcal{T})$  by at least one. (inspect the rules)
  5. At some point the **tableau** only contains **worked off formulae** and **literals**.
  6. Since there are only **finitely many literals** in  $\mathcal{T}$ , so we can only apply  $\mathcal{T}_0 \perp$  a **finite** number of times.
- ▷ **Corollary 11.4.7.**  $\mathcal{T}_0$  induces a **decision procedure** for **validity** in  $PL^0$ .

*Proof:* We combine the results so far

- ▷ 1. By Lemma 11.4.6 it is **decidable** whether  $\vdash_{\mathcal{T}_0} \mathbf{A}$
- 2. By **soundness** (Theorem 11.4.4) and **completeness** (Theorem 11.4.5),  $\vdash_{\mathcal{T}_0} \mathbf{A}$  iff  $\mathbf{A}$  is valid.

**Note:** The proof above only works for the “base  $\mathcal{T}_0$ ” because (only) there the rules do not “copy”. A rule like

$$\frac{\mathbf{A} \Leftrightarrow \mathbf{B}^T}{\begin{array}{c|c} \mathbf{A}^T & \mathbf{A}^F \\ \mathbf{B}^T & \mathbf{B}^F \end{array}}$$

does, and in particular the number of non-worked-off **variables** below the line is larger than above the line. For such rules, we would have a more intricate version of  $\mu$  which – instead of returning a natural number – returns a more complex object; a multiset of numbers. would work here. In our proof we are just assuming that the defined connectives have already eliminated. The **tableau calculus** basically computes the **disjunctive normal form**: every **branch** is a **disjunct** that is a **conjunction** of **literals**. The method relies on the fact that a **DNF** is **unsatisfiable**, iff each **literal** is, i.e. iff each **branch** contains a contradiction in form of a pair of **opposite literals**.

## 11.5 Resolution for Propositional Logic

**A Video Nugget** covering this section can be found at <https://fau.tv/clip/id/23712>.

The next **calculus** is a **test calculus** based on the **conjunctive normal form**: the **resolution calculus**. In contrast to the tableau method, it does not compute the **normal form** as it goes along, but has a pre-processing step that does this and a single **inference rule** that maintains the **normal form**. The goal of **this calculus** is to derive the **empty clause**, which is **unsatisfiable**.

### Another Test Calculus: Resolution

- ▷ **Definition 11.5.1.** A **clause** is a **disjunction**  $l_1^{\alpha_1} \vee \dots \vee l_n^{\alpha_n}$  of **literals**. We will use  $\square$  for the “empty” **disjunction** (no **disjuncts**) and call it the **empty clause**. A **clause** with exactly one **literal** is called a **unit clause**.
- ▷ **Definition 11.5.2 (Resolution Calculus).** The **resolution calculus**  $\mathcal{R}_0$  operates a **clause sets** via a single **inference rule**:

$$\frac{P^T \vee \mathbf{A} \quad P^F \vee \mathbf{B}}{\mathbf{A} \vee \mathbf{B}} \mathcal{R}$$

This **rule** allows to add the **resolvent** (the **clause** below the line) to a **clause set** which contains the two **clauses** above. The **literals**  $P^T$  and  $P^F$  are called **cut literals**.

- ▷ **Definition 11.5.3 (Resolution Refutation).** Let  $S$  be a **clause set**, then we call an  $\mathcal{R}_0$ -**derivation** of  $\square$  from  $S$   **$\mathcal{R}_0$ -refutation** and write  $\mathcal{D}: S \vdash_{\mathcal{R}_0} \square$ .

### Clause Normal Form Transformation (A calculus)

- ▷ **Definition 11.5.4.** We will often write a **clause set**  $\{C_1, \dots, C_n\}$  as  $C_1; \dots; C_n$ ,

use  $S ; T$  for the union of the **clause sets**  $S$  and  $T$ , and  $S ; C$  for the extension by a **clause**  $C$ .

▷ **Definition 11.5.5 (Transformation into Clause Normal Form).** The **CNF transformation calculus**  $CNF_0$  consists of the following four **inference rules** on sets of labeled formulae.

$$\frac{C \vee (A \vee B)^T}{C \vee A^T \vee B^T} \quad \frac{C \vee (A \vee B)^F}{C \vee A^F ; C \vee B^F} \quad \frac{C \vee \neg A^T}{C \vee A^F} \quad \frac{C \vee \neg A^F}{C \vee A^T}$$

▷ **Definition 11.5.6.** We write  $CNF_0(A^\alpha)$  for the set of all **clauses derivable** from  $A^\alpha$  via the **rules** above.

Michael Kohlhase: Artificial Intelligence 1

367

2024-02-08

that the **C**-terms in the definition of the **inference rules** are necessary, since we assumed that the **assumptions** of the **inference rule** must match full **clauses**. The **C** terms are used with the convention that they are optional. So that we can also simplify  $(A \vee B)^T$  to  $A^T \vee B^T$ .

**Background:** The background behind this notation is that  $A$  and  $T \vee A$  are equivalent for any  $A$ . That allows us to interpret the **C**-terms in the **assumptions** as  $T$  and thus leave them out.

The **clause normal form translation** as we have formulated it here is quite frugal; we have left out rules for the **connectives**  $\vee$ ,  $\Rightarrow$ , and  $\Leftrightarrow$ , relying on the fact that formulae containing these **connectives** can be translated into ones without before **CNF transformation**. The advantage of having a **calculus** with few **inference rules** is that we can prove meta properties like **soundness** and **completeness** with less effort (these proofs usually require one case per **inference rule**). On the other hand, adding specialized **inference rules** makes proofs shorter and more readable.

Fortunately, there is a way to have your cake and eat it. **Derivable inference rules** have the property that they are formally redundant, since they do not change the expressive power of the calculus. Therefore we can leave them out when proving meta-properties, but include them when actually using the calculus.

### Derived Rules of Inference

▷ **Definition 11.5.7.** An **inference rule**  $\frac{A_1 \dots A_n}{C}$  is called **derivable** (or a **derived rule**) in a **calculus**  $\mathcal{C}$ , if there is a  $\mathcal{C}$  **derivation**  $A_1, \dots, A_n \vdash_{\mathcal{C}} C$ .

▷ **Idea:** Derived rules make proofs shorter.

▷ **Example 11.5.8.**

$$\frac{\frac{C \vee (A \Rightarrow B)^T}{C \vee \neg A^T \vee B^T}}{C \vee A^F \vee B^T} \quad \sim \quad \frac{C \vee (A \Rightarrow B)^T}{C \vee A^F \vee B^T}$$

▷ **Other Derived CNF Rules:**

$$\frac{C \vee (A \Rightarrow B)^T}{C \vee A^F \vee B^T} \quad \frac{C \vee (A \Rightarrow B)^F}{C \vee A^T ; C \vee B^F} \quad \frac{C \vee (A \wedge B)^T}{C \vee A^T ; C \vee B^T} \quad \frac{C \vee (A \wedge B)^F}{C \vee A^F \vee B^F}$$

Michael Kohlhase: Artificial Intelligence 1

2024-02-08

With these *derivable* rules, theorem proving becomes quite *efficient*. To get a better understanding of the calculus, we look at an example: we prove an axiom of the Hilbert Calculus we have studied above.

### Example: Proving Axiom S with Resolution

▷ **Example 11.5.9.** Clause Normal Form transformation

$$\frac{\frac{\frac{((P \Rightarrow Q \Rightarrow R) \Rightarrow (P \Rightarrow Q) \Rightarrow P \Rightarrow R)^F}{(P \Rightarrow Q \Rightarrow R)^T; ((P \Rightarrow Q) \Rightarrow P \Rightarrow R)^F}}{P^F \vee (Q \Rightarrow R)^T; (P \Rightarrow Q)^T; (P \Rightarrow R)^F}}{P^F \vee Q^F \vee R^T; P^F \vee Q^T; P^T; R^F}$$

Result  $\{P^F \vee Q^F \vee R^T, P^F \vee Q^T, P^T, R^F\}$

▷ **Example 11.5.10.** Resolution Proof

|   |                         |                      |
|---|-------------------------|----------------------|
| 1 | $P^F \vee Q^F \vee R^T$ | initial              |
| 2 | $P^F \vee Q^T$          | initial              |
| 3 | $P^T$                   | initial              |
| 4 | $R^F$                   | initial              |
| 5 | $P^F \vee Q^F$          | resolve 1.3 with 4.1 |
| 6 | $Q^F$                   | resolve 5.1 with 3.1 |
| 7 | $P^F$                   | resolve 2.2 with 6.1 |
| 8 | □                       | resolve 7.1 with 3.1 |

### Clause Set Simplification

▷ **Observation:** Let  $\Delta$  be a *clause set*,  $l$  a *literal*, and  $\Delta'$  be  $\Delta$  where

- ▷ all *clauses*  $l \vee C$  have been removed and
- ▷ and all *clauses*  $\bar{l} \vee C$  have been shortened to  $C$ .

Then  $\Delta$  is *satisfiable*, iff  $\Delta'$  is. We call  $\Delta'$  the *clause set simplification* of  $\Delta$  wrt.  $l$ .

▷ **Corollary 11.5.11.** Adding *clause set simplification* wrt. *unit clauses* to  $\mathcal{R}_0$  does not affect *soundness* and *completeness*.

▷ This is almost always a good idea! (clause set simplification is cheap)

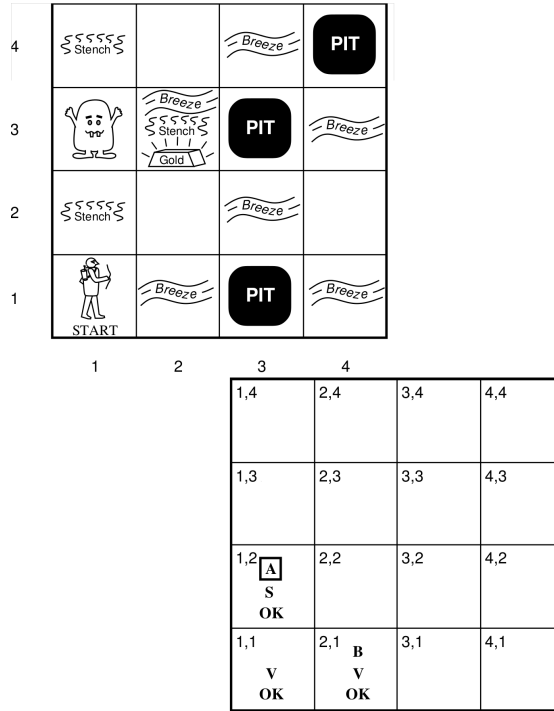

## 11.6 Killing a Wumpus with Propositional Inference

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/23713>.

Let us now consider an extended example, where we also address the question how inference in  $PL^0$  – here *resolution* is embedded into the rational agent metaphor we use in AI-1: we come back to the *Wumpus world*.

### Applying Propositional Inference: Where is the Wumpus?

▷ **Example 11.6.1 (Finding the Wumpus).** The situation and what the agent knows

- ▷ What should the agent do next and why?
- ▷ **One possibility:** Convince yourself that the Wumpus is in [1, 3] and shoot it.
- ▷ What is the general mechanism here? (for the agent function)

Before we come to the general mechanism, we will go into how we would “convince ourselves that the Wumpus is in [1, 3].

### Where is the Wumpus? Our Knowledge

- ▷ **Idea:** We formalize the knowledge about the Wumpus world in  $PL^0$  and use a test calculus to check for entailment.
- ▷ **Simplification:** We worry only about the Wumpus and stench:  
 $S_{i,j} \hat{=} \text{stench in } [i, j], W_{i,j} \hat{=} \text{Wumpus in } [i, j]$ .
- ▷ **Propositions whose value we know:**  $\neg S_{1,1}, \neg W_{1,1}, \neg S_{2,1}, \neg W_{2,1}, S_{1,2}, \neg W_{1,2}$ .
- ▷ **Knowledge about the Wumpus and smell:**  
 From *Cell adjacent to Wumpus: Stench (else: None)*, we get

$$\begin{aligned}
 R_1 &:= \neg S_{1,1} \Rightarrow \neg W_{1,1} \wedge \neg W_{1,2} \wedge \neg W_{2,1} \\
 R_2 &:= \neg S_{2,1} \Rightarrow \neg W_{1,1} \wedge \neg W_{2,1} \wedge \neg W_{2,2} \wedge \neg W_{3,1} \\
 R_3 &:= \neg S_{1,2} \Rightarrow \neg W_{1,1} \wedge \neg W_{1,2} \wedge \neg W_{2,2} \wedge \neg W_{1,3} \\
 R_4 &:= S_{1,2} \Rightarrow (W_{1,3} \vee W_{2,2} \vee W_{1,1}) \\
 &\vdots
 \end{aligned}$$

▷ **To show:**

$$R_1, R_2, R_3, R_4 \models W_{1,3}$$

(we will use resolution)

The first in is to compute the [clause normal form](#) of the relevant [knowledge](#).

## And Now Using Resolution Conventions

▷ We obtain the [clause set](#)  $\Delta$  composed of the following [clauses](#):

▷ **Propositions whose value we know:**  $S_{1,1}^F, W_{1,1}^F, S_{2,1}^F, W_{2,1}^F, S_{1,2}^T, W_{1,2}^F$

▷ **Knowledge about the Wumpus and smell:**

from clauses

$$\begin{aligned}
 R_1 & S_{1,1}^T \vee W_{1,1}^F, S_{1,1}^T \vee W_{1,2}^F, S_{1,1}^T \vee W_{2,1}^F \\
 R_2 & S_{2,1}^T \vee W_{1,1}^F, S_{2,1}^T \vee W_{2,1}^F, S_{2,1}^T \vee W_{2,2}^F, S_{2,1}^T \vee W_{3,1}^F \\
 R_3 & S_{1,2}^T \vee W_{1,1}^F, S_{1,2}^T \vee W_{1,2}^F, S_{1,2}^T \vee W_{2,2}^F, S_{1,2}^T \vee W_{1,3}^F \\
 R_4 & S_{1,2}^F \vee W_{1,3}^T \vee W_{2,2}^T \vee W_{1,1}^T
 \end{aligned}$$

▷ **Negated goal formula:**  $W_{1,3}^F$

Given this [clause normal form](#), we only need to find generate [empty clause](#) via repeated applications of the [resolution rule](#).

## Resolution Proof Killing the Wumpus!

▷ **Example 11.6.2 (Where is the Wumpus).** We show a [derivation](#) that proves that he is in (1, 3).

▷ *Assume the Wumpus is not in (1, 3). Then either there's no stench in (1, 2), or the Wumpus is in some other neighbor cell of (1, 2).*

▷ Parents:  $W_{1,3}^F$  and  $S_{1,2}^F \vee W_{1,3}^T \vee W_{2,2}^T \vee W_{1,1}^T$ .

▷ Resolvent:  $S_{1,2}^F \vee W_{2,2}^T \vee W_{1,1}^T$ .

▷ *There's a stench in (1, 2), so it must be another neighbor.*

▷ Parents:  $S_{1,2}^T$  and  $S_{1,2}^F \vee W_{2,2}^T \vee W_{1,1}^T$ .

▷ Resolvent:  $W_{2,2}^T \vee W_{1,1}^T$ .

▷ *We've been to (1, 1), and there's no Wumpus there, so it can't be (1, 1).*

▷ Parents:  $W_{1,1}^F$  and  $W_{2,2}^T \vee W_{1,1}^T$ .

▷ Resolvent:  $W_{2,2}^T$ .

- ▷ *There is no stench in (2,1) so it can't be (2,2) either, in contradiction.*
  - ▷ Parents:  $S_{2,1}^F$  and  $S_{2,1}^T \vee W_{2,2}^F$ .
  - ▷ Resolvent:  $W_{2,2}^F$ .
  - ▷ Parents:  $W_{2,2}^F$  and  $W_{2,2}^T$ .
  - ▷ Resolvent:  $\square$ .

As **resolution** is **sound**, we have shown that indeed  $R_1, R_2, R_3, R_4 \models W_{1,3}$ .

Now that we have seen how we can use propositional inference to **derive** consequences of the percepts and world knowledge, let us come back to the question of a general mechanism for **agent functions** with propositional inference.

### Where does the Conjecture $W_{1,3}^F$ come from?

- ▷ **Question:** Where did the  $W_{1,3}^F$  come from?
- ▷ **Observation 11.6.3.** *We need a general mechanism for making conjectures.*
- ▷ **Idea:** Interpret the **Wumpus** world as a **search problem**  $\mathcal{P} := \langle \mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$  where
  - ▷ the **states**  $\mathcal{S}$  are given by the **cells** (and **agent** orientation) and
  - ▷ the **actions**  $\mathcal{A}$  by the possible **actions** of the **agent**.

Use **tree search** as the main **agent function** and a **test calculus** for testing all dangers (**pits**), opportunities (**gold**) and the **Wumpus**.
- ▷ **Example 11.6.4 (Back to the Wumpus).** In Example 11.6.1, the **agent** is in  $[1, 2]$ , it has perceived **stench**, and the possible **actions** include **shoot**, and **goForward**. Evaluating either of these leads to the **conjecture**  $W_{1,3}$ . And since  $W_{1,3}$  is **entailed**, the **action shoot** probably comes out best, **heuristically**.
- ▷ **Remark:** Analogous to the **backtracking with inference algorithm** from **CSP**.

Admittedly, the search framework from chapter 6 does not quite cover the **agent function** we have here, since that assumes that the world is **fully observable**, which the **Wumpus world** is emphatically not. But it already gives us a good impression of what would be needed for the “general mechanism”.

### Summary

- ▷ Every propositional formula can be brought into **conjunctive normal form (CNF)**, which can be identified with a set of **clauses**.
- ▷ The **tableau** and **resolution calculi** are deduction procedures based on trying to **derive** a contradiction from the negated theorem (a **closed tableau** or the **empty clause**). They are **refutation complete**, and can be used to prove  $\text{KB} \models \mathbf{A}$  by showing that  $\text{KB} \cup \{\neg \mathbf{A}\}$  is **unsatisfiable**.

**Excursion:** A full analysis of any calculus needs a completeness proof. We will not cover this in AI-1, but provide one for the calculi introduced so far in??.

# Chapter 12

## Formal Systems: Syntax, Semantics, Entailment, and Derivation in General

We will now take a more abstract view and introduce the necessary prerequisites of abstract rule systems. We will also take the opportunity to discuss the quality criteria for calculi.

### Recap: General Aspects of Propositional Logic

▷ **There are many ways to define Propositional Logic:**

- ▷ We chose  $\wedge$  and  $\neg$  as primitive, and many others as defined.
- ▷ We could have used  $\vee$  and  $\neg$  just as well.
- ▷ We could even have used only one **connective** e.g. negated conjunction  $\uparrow$  or disjunction **NOR** and defined  $\wedge$ ,  $\vee$ , and  $\neg$  via  $\uparrow$  and **NOR** respectively.

|            |   |         |         |   |         |
|------------|---|---------|---------|---|---------|
| $\uparrow$ | T | $\perp$ | NOR     | T | $\perp$ |
| T          | F | T       | T       | F | F       |
| $\perp$    | T | T       | $\perp$ | F | T       |

|          |                                      |                                                  |
|----------|--------------------------------------|--------------------------------------------------|
| $\neg a$ | $a \uparrow a$                       | $a \text{ NOR } a$                               |
| $ab$     | $a \uparrow b \uparrow a \uparrow b$ | $a \text{ NOR } ab \text{ NOR } b$               |
| $ab$     | $a \uparrow a \uparrow b \uparrow b$ | $a \text{ NOR } b \text{ NOR } a \text{ NOR } b$ |

- ▷ **Observation:** The set  $wff_0(\mathcal{V}_0)$  of **well-formed propositional formulae** is a **formal language** over the **alphabet** given by  $\mathcal{V}_0$ , the connectives, and brackets.
- ▷ **Recall:** We are mostly interested in
  - ▷ **satisfiability** i.e. whether  $\mathcal{M} \models^\varphi \mathbf{A}$ , and
  - ▷ **entailment** i.e. whether  $\mathbf{A} \models \mathbf{B}$ .
- ▷ **Observation:** In particular, the **inductive/compositional** nature of  $wff_0(\mathcal{V}_0)$  and  $\mathcal{I}_\varphi: wff_0(\mathcal{V}_0) \rightarrow \mathcal{D}_0$  are secondary.
- ▷ **Idea:** Concentrate on language, models  $(\mathcal{M}, \varphi)$ , and satisfiability.

The notion of a **logical system** is at the basis of the field of logic. In its most abstract form, a **logical**

system consists of a formal language, a class of models, and a satisfaction relation between models and expressions of the formal language. The satisfaction relation tells us when an expression is deemed true in this model.

## Logical Systems

- ▷ **Definition 12.0.1.** A **logical system** (or simply a **logic**) is a triple  $\mathcal{L} := \langle \mathcal{L}, \mathcal{K}, \models \rangle$ , where  $\mathcal{L}$  is a formal language,  $\mathcal{K}$  is a set and  $\models \subseteq \mathcal{K} \times \mathcal{L}$ . Members of  $\mathcal{L}$  are called **formulae** of  $\mathcal{L}$ , members of  $\mathcal{K}$  **models** for  $\mathcal{L}$ , and  $\models$  the **satisfaction relation**.
- ▷ **Example 12.0.2 (Propositional Logic).**  $\langle \text{wff}(\Sigma_{PL^0}, \mathcal{V}_{PL^0}), \mathcal{K}, \models \rangle$  is a **logical system**, if we define  $\mathcal{K} := \mathcal{V}_0 \rightarrow \mathcal{D}_0$  (the set of **variable assignments**) and  $\varphi \models \mathbf{A}$  iff  $\mathcal{I}_\varphi(\mathbf{A}) = \top$ .
- ▷ **Definition 12.0.3.** Let  $\langle \mathcal{L}, \mathcal{K}, \models \rangle$  be a **logical system**,  $\mathcal{M} \in \mathcal{K}$  be a **model** and  $\mathbf{A} \in \mathcal{L}$  a **formula**, then we say that  $\mathbf{A}$  is
  - ▷ **satisfied** by  $\mathcal{M}$ , iff  $\mathcal{M} \models \mathbf{A}$ .
  - ▷ **falsified** by  $\mathcal{M}$ , iff  $\mathcal{M} \not\models \mathbf{A}$ .
  - ▷ **satisfiable** in  $\mathcal{K}$ , iff  $\mathcal{M} \models \mathbf{A}$  for some  $\mathcal{M} \in \mathcal{K}$ .
  - ▷ **valid** in  $\mathcal{K}$  (write  $\models \mathbf{A}$ ), iff  $\mathcal{M} \models \mathbf{A}$  for all  $\mathcal{M} \in \mathcal{K}$ .
  - ▷ **falsifiable** in  $\mathcal{K}$ , iff  $\mathcal{M} \not\models \mathbf{A}$  for some  $\mathcal{M} \in \mathcal{K}$ .
  - ▷ **unsatisfiable** in  $\mathcal{K}$ , iff  $\mathcal{M} \not\models \mathbf{A}$  for all  $\mathcal{M} \in \mathcal{K}$ .

Let us now turn to the syntactical counterpart of the entailment relation: **derivability** in a **calculus**. Again, we take care to define the concepts at the general level of **logical systems**. The intuition of a **calculus** is that it provides a set of syntactic rules that allow to reason by considering the form of propositions alone. Such rules are called inference rules, and they can be strung together to derivations — which can alternatively be viewed either as sequences of formulae where all formulae are justified by prior formulae or as trees of **inference rule** applications. But we can also define a **calculus** in the more general setting of **logical systems** as an arbitrary relation on formulae with some general properties. That allows us to abstract away from the homomorphic setup of logics and calculi and concentrate on the basics.

## Derivation Relations and Inference Rules

- ▷ **Definition 12.0.4.** Let  $\mathcal{L} := \langle \mathcal{L}, \mathcal{K}, \models \rangle$  be a **logical system**, then we call a relation  $\vdash \subseteq \mathcal{P}(\mathcal{L}) \times \mathcal{L}$  a **derivation relation** for  $\mathcal{L}$ , if
  - ▷  $\mathcal{H} \vdash \mathbf{A}$ , if  $\mathbf{A} \in \mathcal{H}$  ( $\vdash$  is **proof reflexive**),
  - ▷  $\mathcal{H} \vdash \mathbf{A}$  and  $\mathcal{H}' \cup \{\mathbf{A}\} \vdash \mathbf{B}$  imply  $\mathcal{H} \cup \mathcal{H}' \vdash \mathbf{B}$  ( $\vdash$  is **proof transitive**),
  - ▷  $\mathcal{H} \vdash \mathbf{A}$  and  $\mathcal{H} \subseteq \mathcal{H}'$  imply  $\mathcal{H}' \vdash \mathbf{A}$  ( $\vdash$  is **monotonic** or **admits weakening**).
- ▷ **Definition 12.0.5.** We call  $\langle \mathcal{L}, \mathcal{K}, \models, \mathcal{C} \rangle$  a **formal system**, iff  $\mathcal{L} := \langle \mathcal{L}, \mathcal{K}, \models \rangle$  is a **logical system**, and  $\mathcal{C}$  a **calculus** for  $\mathcal{L}$ .
- ▷ **Definition 12.0.6.** Let  $\mathcal{L}$  be the formal language of a **logical system**, then an **inference rule** over  $\mathcal{L}$  is a **decidable**  $n + 1$  ary relation on  $\mathcal{L}$ . **Inference rules** are

traditionally written as

$$\frac{\mathbf{A}_1 \dots \mathbf{A}_n}{\mathbf{C}} \mathcal{N}$$

where  $\mathbf{A}_1, \dots, \mathbf{A}_n$  and  $\mathbf{C}$  are formula schemata for  $\mathcal{L}$  and  $\mathcal{N}$  is a name.

The  $\mathbf{A}_i$  are called **assumptions** of  $\mathcal{N}$ , and  $\mathbf{C}$  is called its **conclusion**.

▷ **Definition 12.0.7.** An inference rule without assumptions is called an **axiom**.

▷ **Definition 12.0.8.** Let  $\mathcal{L} := \langle \mathcal{L}, \mathcal{K}, \models \rangle$  be a logical system, then we call a set  $\mathcal{C}$  of inference rules over  $\mathcal{L}$  a **calculus** (or **inference system**) for  $\mathcal{L}$ .

With formula schemata we mean representations of sets of formulae, we use boldface uppercase letters as (meta)-variables for formulae, for instance the formula schema  $\mathbf{A} \Rightarrow \mathbf{B}$  represents the set of formulae whose head is  $\Rightarrow$ .

## Derivations

▷ **Definition 12.0.9.** Let  $\mathcal{L} := \langle \mathcal{L}, \mathcal{K}, \models \rangle$  be a logical system and  $\mathcal{C}$  a calculus for  $\mathcal{L}$ , then a  **$\mathcal{C}$ -derivation** of a formula  $\mathbf{C} \in \mathcal{L}$  from a set  $\mathcal{H} \subseteq \mathcal{L}$  of hypotheses (write  $\mathcal{H} \vdash_{\mathcal{C}} \mathbf{C}$ ) is a sequence  $\mathbf{A}_1, \dots, \mathbf{A}_m$  of  $\mathcal{L}$ -formulae, such that

▷  $\mathbf{A}_m = \mathbf{C}$ , (derivation culminates in  $\mathbf{C}$ )

▷ for all  $1 \leq i \leq m$ , either  $\mathbf{A}_i \in \mathcal{H}$ , or (hypothesis)

▷ there is an inference rule  $\frac{\mathbf{A}_{l_1} \dots \mathbf{A}_{l_k}}{\mathbf{A}_i}$  in  $\mathcal{C}$  with  $l_j < i$  for all  $j \leq k$ . (rule application)

We can also see a derivation as a **derivation tree**, where the  $\mathbf{A}_{l_j}$  are the children of the node  $\mathbf{A}_k$ .

▷ **Example 12.0.10.**

In the propositional Hilbert calculus  $\mathcal{H}^0$  we have the derivation  $P \vdash_{\mathcal{H}^0} Q \Rightarrow P$ : the sequence is  $P \Rightarrow Q \Rightarrow P, P, Q \Rightarrow P$  and the corresponding tree on the right.

$$\frac{\frac{P \Rightarrow Q \Rightarrow P \quad K}{P \Rightarrow Q \Rightarrow P} \quad P}{Q \Rightarrow P} MP$$

**Inference rules** are relations on formulae represented by formula schemata (where boldface, uppercase letters are used as meta-variables for formulae). For instance, in Example 12.0.10 the inference rule  $\frac{\mathbf{A} \Rightarrow \mathbf{B} \quad \mathbf{A}}{\mathbf{B}}$  was applied in a situation, where the meta-variables  $\mathbf{A}$  and  $\mathbf{B}$  were instantiated by the formulae  $P$  and  $Q \Rightarrow P$ .

As axioms do not have assumptions, they can be added to a derivation at any time. This is just what we did with the axioms in Example 12.0.10.

## Formal Systems

▷ Let  $\langle \mathcal{L}, \mathcal{K}, \models \rangle$  be a logical system and  $\mathcal{C}$  a calculus, then  $\vdash_{\mathcal{C}}$  is a **derivation relation** and thus  $\langle \mathcal{L}, \mathcal{K}, \models, \vdash_{\mathcal{C}} \rangle$  a **derivation system**.

- ▷ Therefore we will sometimes also call  $\langle \mathcal{L}, \mathcal{K}, \models, \mathcal{C} \rangle$  a **formal system**, iff  $\mathcal{L} := \langle \mathcal{L}, \mathcal{K}, \models \rangle$  is a **logical system**, and  $\mathcal{C}$  a **calculus** for  $\mathcal{L}$ .
- ▷ **Definition 12.0.11.** Let  $\mathcal{C}$  be a **calculus**, then a  $\mathcal{C}$ -**derivation**  $\emptyset \vdash_{\mathcal{C}} \mathbf{A}$  is called a **proof** of  $\mathbf{A}$  and if one exists (write  $\vdash_{\mathcal{C}} \mathbf{A}$ ) then  $\mathbf{A}$  is called a  **$\mathcal{C}$ -theorem**.
- Definition 12.0.12.** The act of finding a **proof** for a **formula**  $\mathbf{A}$  is called **proving**  $\mathbf{A}$ .
- ▷ **Definition 12.0.13.** An **inference rule**  $\mathcal{I}$  is called **admissible** in a **calculus**  $\mathcal{C}$ , if the extension of  $\mathcal{C}$  by  $\mathcal{I}$  does not yield new **theorems**.
- ▷ **Definition 12.0.14.** An **inference rule**  $\frac{\mathbf{A}_1 \dots \mathbf{A}_n}{\mathbf{C}}$  is called **derivable** (or a **derived rule**) in a **calculus**  $\mathcal{C}$ , if there is a  $\mathcal{C}$  **derivation**  $\mathbf{A}_1, \dots, \mathbf{A}_n \vdash_{\mathcal{C}} \mathbf{C}$ .
- ▷ **Observation 12.0.15.** *Derivable inference rules are admissible, but not the other way around.*

The notion of a **formal system** encapsulates the most general way we can conceptualize a system with a **calculus**, i.e. a system in which we can do “formal reasoning”.

# Chapter 13

## Propositional Reasoning: SAT Solvers

### 13.1 Introduction

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/25019>.

#### Reminder: Our Agenda for Propositional Logic

- ▷ **chapter 10**: Basic definitions and concepts; machine-oriented calculi
  - ▷ Sets up the framework. **Tableaux** and **resolution** are the quintessential reasoning procedures underlying most successful **SAT solvers**.
- ▷ **This chapter**: The **Davis Putnam procedure** and **clause learning**.
  - ▷ State-of-the-art **algorithms** for reasoning about propositional logic, and an important observation about how they behave.

#### SAT: The Propositional Satisfiability Problem

- ▷ **Definition 13.1.1.** The **SAT problem (SAT)**: Given a **propositional formula  $A$** , decide whether or not  **$A$**  is **satisfiable**. We denote the class of all **SAT problems** with **SAT**
- ▷ The **SAT problem** was the first problem proved to be **NP-complete**!
- ▷  **$A$**  is commonly assumed to be in **CNF**. This is **without loss of generality**, because any  **$A$**  can be transformed into a satisfiability-equivalent **CNF** formula (cf. chapter 10) in **polynomial time**.
- ▷ Active research area, annual **SAT** conference, lots of tools etc. available: <http://www.satlive.org/>
- ▷ **Definition 13.1.2.** Tools addressing **SAT** are commonly referred to as **SAT solvers**.

- ▷ **Recall:** To decide whether  $\text{KB} \models \mathbf{A}$ , decide satisfiability of  $\theta := \text{KB} \cup \{\neg \mathbf{A}\}$ :  $\theta$  is unsatisfiable iff  $\text{KB} \models \mathbf{A}$ .
- ▷ **Consequence:** Deduction can be performed using SAT solvers.

## SAT vs. CSP

- ▷ **Recall:** Constraint network  $\langle V, D, C \rangle$  has variables  $v \in V$  with finite domains  $D_v \in D$ , and binary constraints  $C_{uv} \in C$  which are relations over  $u, v$  specifying the permissible combined assignments to  $u$  and  $v$ . One extension is to allow constraints of higher arity.
- ▷ **Observation 13.1.3 (SAT: A kind of CSP).** SAT can be viewed as a CSP problem in which all variable domains are Boolean, and the constraints have unbounded arity.
- ▷ **Theorem 13.1.4 (Encoding CSP as SAT).** Given any constraint network  $\mathcal{C}$ , we can in low order polynomial time construct a CNF formula  $\mathbf{A}(\mathcal{C})$  that is satisfiable iff  $\mathcal{C}$  is solvable.
- ▷ **Proof:** We design a formula, relying on known transformation to CNF
  1. encode multi-XOR for each variable
  2. encode each constraint by DNF over relation
  3. Running time:  $\mathcal{O}(nd^2 + md^2)$  where  $n$  is the number of variables,  $d$  the domain size, and  $m$  the number of constraints.
- ▷ **Upshot:** Anything we can do with CSP, we can (in principle) do with SAT.

## Example Application: Hardware Verification

- ▷ **Example 13.1.5 (Hardware Verification).**

- ▷ Counter, repeatedly from  $c = 0$  to  $c = 2$ .
- ▷ 2 bits  $x_1$  and  $x_0$ ;  $c = 2 * x_1 + x_0$ .
- ▷ (FF  $\hat{=}$  Flip-Flop, D  $\hat{=}$  Data IN, CLK  $\hat{=}$  Clock)
- ▷ **To Verify:** If  $c < 3$  in current clock cycle, then  $c < 3$  in next clock cycle.
- ▷ **Step 1:** Encode into propositional logic.
  - ▷ **Propositions:**  $x_1, x_0$ ; and  $y_1, y_0$  (value in next cycle).
  - ▷ **Transition relation:**  $y_1 \Leftrightarrow y_0$ ;  $y_0 \Leftrightarrow (\neg(x_1 \vee x_0))$ .
  - ▷ **Initial state:**  $\neg(x_1 \wedge x_0)$ .
  - ▷ **Error property:**  $x_1 \wedge y_0$ .
- ▷ **Step 2:** Transform to CNF, encode as a clause set  $\Delta$ .

▷ **Cluses:**  $y_1^F \vee x_0^T, y_1^T \vee x_0^F, y_0^T \vee x_1^T \vee x_0^T, y_0^F \vee x_1^F, y_0^F \vee x_0^F, x_1^F \vee x_0^F, y_1^T, y_0^T$ .

▷ **Step 3:** Call a SAT solver (up next).

## Our Agenda for This Chapter

- ▷ **The Davis-Putnam (Logemann-Loveland) Procedure:** How to systematically test satisfiability?
  - ▷ The quintessential SAT solving procedure, DPLL.
- ▷ **DPLL is (A Restricted Form of) Resolution:** How does this relate to what we did in the last chapter?
  - ▷ mathematical understanding of DPLL.
- ▷ **Why Did Unit Propagation Yield a Conflict?:** How can we analyze which mistakes were made in “dead” search branches?
  - ▷ Knowledge is power, see next.
- ▷ **Clause Learning:** How can we learn from our mistakes?
  - ▷ One of the key concepts, perhaps *the* key concept, underlying the success of SAT.
- ▷ **Phase Transitions – Where the Really Hard Problems Are:** Are *all* formulas “hard” to solve?
  - ▷ The answer is “no”. And in some cases we can figure out exactly when they are/aren’t hard to solve.

## 13.2 The Davis-Putnam (Logemann-Loveland) Procedure

A Video Nugget covering this section can be found at <https://fau.tv/clip/id/25026>.

### The DPLL Procedure

- ▷ **Definition 13.2.1.** The Davis Putnam procedure (DPLL) is a SAT solver called on a clause set  $\Delta$  and the empty assignment  $\epsilon$ . It interleaves unit propagation (UP) and splitting:

**function** DPLL( $\Delta, I$ ) **returns** a partial assignment  $I$ , or “unsatisfiable”

```
/* Unit Propagation (UP) Rule: */
```

```
 Δ' := a copy of Δ ; $I' := I$
```

```
while Δ' contains a unit clause $C = P^\alpha$ do
```

```
 extend I' with $[\alpha/P]$, clause-set simplify Δ'
```

```
/* Termination Test: */
```

```
if $\square \in \Delta'$ then return “unsatisfiable”
```

```

if $\Delta' = \{\}$ then return I'
/* Splitting Rule: */
select some proposition P for which I' is not defined
 $I'' := I'$ extended with one truth value for P ; $\Delta'' :=$ a copy of Δ' ; simplify Δ''
if $I''' := \text{DPLL}(\Delta'', I'') \neq$ "unsatisfiable" then return I'''
 $I'' := I'$ extended with the other truth value for P ; $\Delta'' := \Delta'$; simplify Δ''
return $\text{DPLL}(\Delta'', I'')$

```

▷ In practice, of course one uses flags etc. instead of "copy".

## DPLL: Example (Vanilla1)

▷ **Example 13.2.2 (UP and Splitting).** Let  $\Delta := (P^T \vee Q^T \vee R^F; P^F \vee Q^F; R^T; P^T \vee Q^F)$

1. UP Rule:  $R \rightarrow T$   
 $P^T \vee Q^T; P^F \vee Q^F; P^T \vee Q^F$
2. Splitting Rule:
 

|                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ol style="list-style-type: none"> <li>2a. <math>P \rightarrow F</math><br/><math>Q^T; Q^F</math></li> <li>3a. UP Rule: <math>Q \rightarrow T</math><br/><math>\square</math><br/><b>returning "unsatisfiable"</b></li> </ol> | <ol style="list-style-type: none"> <li>2b. <math>P \rightarrow T</math><br/><math>Q^F</math></li> <li>3b. UP Rule: <math>Q \rightarrow F</math><br/>clause set empty<br/><b>returning "<math>R \rightarrow T, P \rightarrow T, Q \rightarrow F</math>"</b></li> </ol> |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## DPLL: Example (Vanilla2)

▷ **Observation:** Sometimes UP is all we need.

▷ **Example 13.2.3.** Let  $\Delta := (Q^F \vee P^F; P^T \vee Q^F \vee R^F \vee S^F; Q^T \vee S^F; R^T \vee S^F; S^T)$

1. UP Rule:  $S \rightarrow T$   
 $Q^F \vee P^F; P^T \vee Q^F \vee R^F; Q^T; R^T$
2. UP Rule:  $Q \rightarrow T$   
 $P^F; P^T \vee R^F; R^T$
3. UP Rule:  $R \rightarrow T$   
 $P^F; P^T$
4. UP Rule:  $P \rightarrow T$   
 $\square$

## DPLL: Example (Redundance1)

▷ **Example 13.2.4.** We introduce some nasty redundancy to make DPLL slow.  
 $\Delta := (P^F \vee Q^F \vee R^T; P^F \vee Q^F \vee R^F; P^F \vee Q^T \vee R^T; P^F \vee Q^T \vee R^F)$   
 DPLL on  $\Delta$ ;  $\Theta$  with  $\Theta := (X_1^T \vee \dots \vee X_n^T; X_1^F \vee \dots \vee X_n^F)$

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 390 2024-02-08

### Properties of DPLL

- ▷ **Unsatisfiable case:** What can we say if “unsatisfiable” is returned?
  - ▷ In this case, we know that  $\Delta$  is **unsatisfiable**: Unit propagation is *sound*, in the sense that it does not reduce the set of solutions.
- ▷ **Satisfiable case:** What can we say when a partial interpretation  $I$  is returned?
  - ▷ Any extension of  $I$  to a complete interpretation satisfies  $\Delta$ . (By construction,  $I$  suffices to satisfy all **clauses**.)
- ▷ Déjà Vu, Anybody?
- ▷ DPLL  $\hat{=}$  **backtracking with inference**, where inference  $\hat{=}$  **unit propagation**.
  - ▷ **Unit propagation** is **sound**: It does not reduce the set of solutions.
  - ▷ **Running time** is **exponential** in worst case, good variable/value selection strategies required.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 391 2024-02-08

## 13.3 DPLL $\hat{=}$ (A Restricted Form of) Resolution

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/27022>.

In the last slide we have discussed the semantic properties of the DPLL procedure: DPLL is (refutation) **sound** and **complete**. Note that this is a theoretical result in the sense that the **algorithm** is, but that does not mean that a particular **implementation** of DPLL might not contain **bugs** that affect **soundness** and **completeness**.

In the **satisfiable** case, DPLL returns a satisfying **variable assignment**, which we can check (in low-order **polynomial** time) but in the **unsatisfiable** case, it just reports on the fact that it has tried all branches and found nothing. This is clearly unsatisfactory, and we will address this situation now by presenting a way that DPLL can output a **resolution proof** in the **unsatisfiable** case.

## UP $\hat{=}$ Unit Resolution

- ▷ **Observation:** The **unit propagation (UP)** rule corresponds to a **calculus**:

```
while Δ' contains a unit clause $\{l\}$ do
 extend I' with the respective truth value for the proposition underlying l
 simplify Δ' /* remove false literals */
```

- ▷ **Definition 13.3.1 (Unit Resolution).** **Unit resolution (UR)** is the **test calculus** consisting of the following **inference rule**:

$$\frac{C \vee P^\alpha \quad P^\beta \quad \alpha \neq \beta}{C} \text{UR}$$

- ▷ **Unit propagation  $\hat{=}$  resolution** restricted to cases where one parent is **unit clause**.
- ▷ **Observation 13.3.2 (Soundness).** **UR is refutation sound.** (*since resolution is*)
- ▷ **Observation 13.3.3 (Completeness).** **UR is not refutation complete (alone).**
- ▷ **Example 13.3.4.**  $P^T \vee Q^T$ ;  $P^T \vee Q^F$ ;  $P^F \vee Q^T$ ;  $P^F \vee Q^F$  is **unsatisfiable** but **UR** cannot **derive** the **empty clause**  $\square$ .
- ▷ **UR** makes only limited inferences, as long as there are **unit clauses**. It does not guarantee to infer everything that can be inferred.

## DPLL vs. Resolution

- ▷ **Definition 13.3.5.** We define the **number of decisions** of a **DPLL** run as the total number of times a truth value was set by either **unit propagation** or **splitting**.
- ▷ **Theorem 13.3.6.** *If DPLL returns “unsatisfiable” on  $\Delta$ , then  $\Delta \vdash_{\mathcal{R}_0} \square$  with a resolution proof whose length is at most the number of decisions.*
- ▷ **Proof:** Consider first **DPLL** without **UP**
1. Consider any **leaf node**  $N$ , for proposition  $X$ , both of whose truth values directly result in a **clause**  $C$  that has become **empty**.
  2. Then for  $X = F$  the respective **clause**  $C$  must contain  $X^T$ ; and for  $X = T$  the respective **clause**  $C$  must contain  $X^F$ . Thus we can resolve these two **clauses** to a **clause**  $C(N)$  that does not contain  $X$ .
  3.  $C(N)$  can contain only the negations of the decision **literals**  $l_1, \dots, l_k$  above  $N$ . Remove  $N$  from the **tree**, then iterate the argument. Once the tree is empty, we have derived the **empty clause**.
  4. **Unit propagation** can be simulated via applications of the **splitting** rule, choosing a proposition that is constrained by a **unit clause**: One of the two truth values then immediately yields an **empty clause**.

### DPLL vs. Resolution: Example (Vanilla2)

▷ **Observation:** The proof of Theorem 13.3.6 is **constructive**, so we can use it as a method to read of a **resolution proof** from a **DPLL trace**.

▷ **Example 13.3.7.** We follow the steps in the proof of Theorem 13.3.6 for  $\Delta := (Q^F \vee P^F; P^T \vee Q^F \vee R^F \vee S^F; Q^T \vee S^F; R^T \vee S^F; S^T)$

**DPLL:** (Without UP; leaves annotated with clauses that became empty)

**Resolution proof from that DPLL tree:**

▷ **Intuition:** From a (top-down) **DPLL tree**, we generate a (bottom-up) **resolution proof**.

2024-02-08

For reference, we give the full proof here.

**Theorem 13.3.8.** If DPLL returns “unsatisfiable” on a clause set  $\Delta$ , then  $\Delta \vdash_{\mathcal{R}_0} \square$  with a  $\mathcal{R}_0$ -derivation whose length is at most the number of decisions.

*Proof:* Consider first DPLL with no unit propagation.

1. If the search tree is not empty, then there exists a leaf node  $N$ , i.e., a node associated to proposition  $X$  so that, for each value of  $X$ , the partial assignment directly results in an empty clause.
2. Denote the parent decisions of  $N$  by  $L_1, \dots, L_k$ , where  $L_i$  is a literal for proposition  $X_i$  and the search node containing  $X_i$  is  $N_i$ .
3. Denote the empty clause for  $X$  by  $C(N, X)$ , and denote the empty clause for  $X^F$  by  $C(N, X^F)$ .
4. For each  $x \in \{X^T, X^F\}$  we have the following properties:
  1.  $x^F \in C(N, x)$ ; and
  2.  $C(N, x) \subseteq \{x^F, \overline{L_1}, \dots, \overline{L_k}\}$ .

Due to , we can resolve  $C(N, X)$  with  $C(N, X^F)$ ; denote the outcome clause by  $C(N)$ .
5. We obviously have that (1)  $C(N) \subseteq \{\overline{L_1}, \dots, \overline{L_k}\}$ .
6. The proof now proceeds by removing  $N$  from the search tree and attaching  $C(N)$  at the  $L_k$  branch of  $N_k$ , in the role of  $C(N_k, L_k)$  as above. Then we select the next leaf node  $N'$  and iterate the argument; once the tree is empty, by (1) we have derived the empty clause. What we need to show is that, in each step of this iteration, we preserve the properties (a) and (b) for all leaf nodes. Since we did not change anything in other parts of the tree, the only node we need to show this for is  $N' := N_k$ .
7. Due to (1), we have (b) for  $N_k$ . But we do not necessarily have (a):  $C(N) \subseteq \{\overline{L_1}, \dots, \overline{L_k}\}$ , but there are cases where  $\overline{L_k} \notin C(N)$  (e.g., if  $X_k$  is not contained in any clause and thus

branching over it was completely unnecessary). If so, however, we can simply remove  $N_k$  and all its descendants from the tree as well. We attach  $C(N)$  at the  $L_{(k-1)}$  branch of  $N_{(k-1)}$ , in the role of  $C(N_{(k-1)}, L_{(k-1)})$ . If  $\overline{L_{(k-1)}} \in C(N)$  then we have (a) for  $N' := N_{(k-1)}$  and can stop. If  $L_{(k-1)} \notin C(N)$ , then we remove  $N_{(k-1)}$  and so forth, until either we stop with (a), or have removed  $N_1$  and thus must already have derived the empty clause (because  $C(N) \subseteq \{\overline{L_1}, \dots, \overline{L_k}\} \setminus \{\overline{L_1}, \dots, \overline{L_k}\}$ ).

8. **Unit propagation** can be simulated via applications of the **splitting** rule, choosing a proposition that is constrained by a **unit clause**: One of the two truth values then immediately yields an **empty clause**.

### DPLL vs. Resolution: Discussion

- ▷ **So What?:** The theorem we just proved helps to *understand* DPLL: DPLL is an **efficient** practical method for conducting **resolution proofs**.
- ▷ **In fact:**  $\text{DPLL} \hat{=} \text{tree resolution}$ .
- ▷ **Definition 13.3.9.** In a **tree resolution**, each **derived clause**  $C$  is used only once (at its **parent**).
- ▷ **Problem:** The same  $C$  must be **derived** anew every time it is used!
- ▷ **This is a fundamental weakness:** There are inputs  $\Delta$  whose shortest **tree resolution** proof is **exponentially** longer than their shortest (general) **resolution proof**.
- ▷ **Intuitively:** DPLL makes the same mistakes over and over again.
- ▷ **Idea:** DPLL should learn from its mistakes on one search **branch**, and apply the learned knowledge to other **branches**.
- ▷ **To the rescue:** **clause learning** (up next)

**Excursion:** Practical **SAT solvers** use a technique called **CDCL** that analyzes failure and learns from that in terms of inferred clauses. Unfortunately, we cannot cover this in AI-1.??.

## 13.4 Conclusion

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/25090>.

### Summary

- ▷ **SAT solvers** decide satisfiability of CNF formulas. This can be used for deduction, and is highly successful as a general problem solving technique (e.g., in **verification**).
- ▷  $\text{DPLL} \hat{=} \text{backtracking}$  with inference performed by **unit propagation (UP)**, which iteratively instantiates **unit clauses** and simplifies the **formula**.
- ▷ DPLL proofs of unsatisfiability correspond to a restricted form of **resolution**. The restriction forces DPLL to “makes the same mistakes over again”.
- ▷ **Implication graphs** capture how **UP derives** conflicts. Their analysis enables us to do **clause learning**. DPLL with **clause learning** is called **CDCL**. It corresponds to full

resolution, not “making the same mistakes over again”.

- ▷ CDCL is *state of the art* in applications, routinely solving formulas with millions of propositions.
- ▷ In particular random formula distributions, typical problem hardness is characterized by *phase transitions*.

## State of the Art in SAT

### ▷ SAT competitions:

- ▷ Since beginning of the 90s <http://www.satcompetition.org/>
- ▷ *random vs. industrial vs. handcrafted benchmarks*.
- ▷ Largest industrial instances: > 1.000.000 propositions.

### ▷ State of the art is CDCL:

- ▷ Vastly superior on handcrafted and industrial *benchmarks*.
- ▷ Key techniques: *clause learning!* Also: *Efficient implementation (UP!)*, good *branching heuristics*, random restarts, portfolios.

### ▷ What about local search?:

- ▷ Better on random instances.
- ▷ No “dramatic” progress in last decade.
- ▷ Parameters are difficult to adjust.

## But – What About Local Search for SAT?

- ▷ There’s a wealth of research on local search for SAT, e.g.:
- ▷ **Definition 13.4.1.** The *GSAT algorithm OUTPUT*: a satisfying truth assignment of  $\Delta$ , if found

```

function GSAT (Δ , MaxFlips MaxTries
 for $i := 1$ to MaxTries
 $I :=$ a randomly-generated truth assignment
 for $j := 1$ to MaxFlips
 if I satisfies Δ then return I
 $X :=$ a proposition reversing whose truth assignment gives
 the largest increase in the number of satisfied clauses
 $I := I$ with the truth assignment of X reversed
 end for
 end for
 return “no satisfying assignment found”

```

- ▷ **local search** is not as successful in SAT applications, and the underlying ideas are very similar to those presented in section 6.6 (Not covered here)

## Topics We Didn't Cover Here

- ▷ **Variable/value selection heuristics**: A whole zoo is out there.
- ▷ **Implementation techniques**: One of the most intensely researched subjects. Famous “watched literals” technique for UP had huge practical impact.
- ▷ **Local search**: In space of all truth value assignments. GSAT (slide 398) had huge impact at the time (1992), caused huge amount of follow-up work. Less intensely researched since clause learning hit the scene in the late 90s.
- ▷ **Portfolios**: How to combine several SAT solvers efficiently?
- ▷ **Random restarts**: Tackling heavy-tailed runtime distributions.
- ▷ **Tractable SAT**: Polynomial-time sub-classes (most prominent: 2-SAT, Horn formulas).
- ▷ **MaxSAT**: Assign weight to each clause, maximize weight of satisfied clauses (= optimization version of SAT).
- ▷ **Resolution special cases**: There's a universe in between unit resolution and full resolution: trade off inference vs. search.
- ▷ **Proof complexity**: Can one resolution special case  $X$  simulate another one  $Y$  polynomially? Or is there an exponential separation (example families where  $X$  is exponentially less efficient than  $Y$ )?

### Suggested Reading:

- *Chapter 7: Logical Agents*, Section 7.6.1 [RN09].
  - Here, RN describe DPLL, i.e., basically what I cover under “The Davis-Putnam (Logemann-Loveland) Procedure”.
  - That’s the only thing they cover of this Chapter’s material. (And they even mark it as “can be skimmed on first reading”.)
  - This does not do the state of the art in SAT any justice.
- *Chapter 7: Logical Agents*, Sections 7.6.2, 7.6.3, and 7.7 [RN09].
  - Sections 7.6.2 and 7.6.3 say a few words on local search for SAT, which I recommend as additional background reading. Section 7.7 describes in quite some detail how to build an agent using propositional logic to take decisions; nice background reading as well.

# Chapter 14

## First-Order Predicate Logic

### 14.1 Motivation: A more Expressive Language

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/25091>.

#### Let's Talk About Blocks, Baby ...

▷ **Question:** What do you see here?

▷ **You say:** "All blocks are red"; "All blocks are on the table"; "A is a block".

▷ **And now:** Say it in **propositional logic**!

▷ **Answer:** "isRedA", "isRedB", ..., "onTableA", "onTableB", ..., "isBlockA", ...

▷ **Wait a sec!:** Why don't we just say, e.g., "AllBlocksAreRed" and "isBlockA"?

▷ **Problem:** Could we conclude that A is red? (No)

These statements are atomic (just strings); their inner structure ("all blocks", "is a block") is not captured.

▷ **Idea:** **Predicate Logic (PL)** extends **propositional logic** with the ability to explicitly speak about objects and their properties.

▷ **How?:** Variables ranging over objects, predicates describing object properties, ...

▷ **Example 14.1.1.** " $\forall x.\text{block}(x) \Rightarrow \text{red}(x)$ "; " $\text{block}(\mathbf{A})$ "

#### Let's Talk About the Wumpus Instead?

▷

**Percepts:** [*Stench, Breeze, Glitter, Bump, Scream*]

- ▷ Cell adjacent to **Wumpus**: *Stench* (else: *None*).
- ▷ Cell adjacent to **Pit**: *Breeze* (else: *None*).
- ▷ Cell that contains gold: *Glitter* (else: *None*).
- ▷ You walk into a wall: *Bump* (else: *None*).
- ▷ **Wumpus** shot by arrow: *Scream* (else: *None*).

▷ Say, in **propositional logic**: “Cell adjacent to **Wumpus**: *Stench*.”

- ▷  $W_{1,1} \Rightarrow S_{1,2} \wedge S_{2,1}$
- ▷  $W_{1,2} \Rightarrow S_{2,2} \wedge S_{1,1} \wedge S_{1,3}$
- ▷  $W_{1,3} \Rightarrow S_{2,3} \wedge S_{1,2} \wedge S_{1,4}$
- ▷ ...

▷ **Note:** Even when we *can* describe the problem suitably, for the desired reasoning, the propositional formulation typically is way too large to write (by hand).

▷ **PL1 solution:** “ $\forall x. \text{Wumpus}(x) \Rightarrow (\forall y. \text{adj}(x, y) \Rightarrow \text{stench}(y))$ ”

## Blocks/Wumpus, Who Cares? Let's Talk About Numbers!

▷ Even worse!

▷ **Example 14.1.2 (Integers).** A limited vocabulary to talk about these

- ▷ The objects:  $\{1, 2, 3, \dots\}$ .
- ▷ Predicate 1: “ $\text{even}(x)$ ” should be true iff  $x$  is even.
- ▷ Predicate 2: “ $\text{eq}(x, y)$ ” should be true iff  $x = y$ .
- ▷ Function:  $\text{succ}(x)$  maps  $x$  to  $x + 1$ .

▷ **Old problem:** Say, in **propositional logic**, that “ $1 + 1 = 2$ ”.

- ▷ Inner structure of vocabulary is ignored (cf. “AllBlocksAreRed”).
- ▷ PL1 solution: “ $\text{eq}(\text{succ}(1), 2)$ ”.

▷ **New Problem:** Say, in **propositional logic**, “if  $x$  is even, so is  $x + 2$ ”.

- ▷ It is impossible to speak about **infinite** sets of objects!
- ▷ PL1 solution: “ $\forall x. \text{even}(x) \Rightarrow \text{even}(\text{succ}(\text{succ}(x)))$ ”.

## Now We're Talking

▷ **Example 14.1.3.**

$$\forall n. \text{gt}(n, 2) \Rightarrow \neg(\exists a, b, c. \text{eq}(\text{plus}(\text{pow}(a, n), \text{pow}(b, n)), \text{pow}(c, n)))$$

Read: *Forall  $n > 2$ , there are  $a, b, c$ , such that  $a^n + b^n = c^n$*  (Fermat's last theorem)

- ▷ **Theorem proving in PL1:** Arbitrary theorems, in principle.
- ▷ Fermat's last theorem is of course infeasible, but interesting theorems can and have been proved automatically.
  - ▷ See [http://en.wikipedia.org/wiki/Automated\\_theorem\\_proving](http://en.wikipedia.org/wiki/Automated_theorem_proving).
  - ▷ **Note:** Need to axiomatize "Plus", "PowerOf", "Equals". See [http://en.wikipedia.org/wiki/Peano\\_axioms](http://en.wikipedia.org/wiki/Peano_axioms)

## What Are the Practical Relevance/Applications?

- ▷ ... **even asking this question is a sacrilege:**
- ▷ (Quotes from Wikipedia)
- ▷ *"In Europe, logic was first developed by Aristotle. Aristotelian logic became widely accepted in science and mathematics."*
  - ▷ *"The development of logic since Frege, Russell, and Wittgenstein had a profound influence on the practice of philosophy and the perceived nature of philosophical problems, and Philosophy of mathematics."*
  - ▷ *"During the later medieval period, major efforts were made to show that Aristotle's ideas were compatible with Christian faith."*
  - ▷ (In other words: the church issued for a long time that Aristotle's ideas were incompatible with Christian faith.)

## What Are the Practical Relevance/Applications?

- ▷ **You're asking it anyhow:**
- ▷ **Logic programming.** Prolog et al.
  - ▷ **Databases.** Deductive databases where elements of logic allow to conclude additional facts. Logic is tied deeply with database theory.
  - ▷ Semantic technology. Mega-trend since > a decade. Use PL1 fragments to annotate data sets, facilitating their use and analysis.
  - ▷ Prominent PL1 fragment: [Web Ontology Language OWL](#).
  - ▷ Prominent data set: The [WWW](#). (semantic web)
  - ▷ **Assorted quotes on Semantic Web and OWL:**

- ▷ *The brain of humanity.*
- ▷ *The Semantic Web will never work.*
- ▷ *A TRULY meaningful way of interacting with the Web may finally be here: the Semantic Web. The idea was proposed 10 years ago. A triumvirate of internet heavyweights – Google, Twitter, and Facebook – are making it real.*

## (A Few) Semantic Technology Applications

### Web Queries

### Context-Aware Apps

### Jeopardy (IBM Watson)

### Healthcare

## Our Agenda for This Topic

- ▷ **This Chapter:** Basic definitions and concepts; normal forms.
  - ▷ Sets up the framework and basic operations.
  - ▷ **Syntax:** How to write PL1 formulas? (Obviously required)
  - ▷ **Semantics:** What is the meaning of PL1 formulas? (Obviously required.)
  - ▷ **Normal Forms:** What are the basic normal forms, and how to obtain them? (Needed for algorithms, which are defined on these normal forms.)
- ▷ **Next Chapter:** Compilation to propositional reasoning; unification; lifted resolution/tableau.
  - ▷ Algorithmic principles for reasoning about predicate logic.

## 14.2 First-Order Logic

**A Video Nugget** covering this section can be found at <https://fau.tv/clip/id/25093>.

First-order logic is the most widely used **formal systems** for modelling knowledge and **inference** processes. It strikes a very good bargain in the trade-off between expressivity and conceptual and **computational complexity**. To many people **first-order logic** is “the logic”, i.e. the only **logic** worth considering, its applications range from the foundations of **mathematics** to **natural language semantics**.

### First-Order Predicate Logic ( $PL^1$ )

---

- ▷ **Coverage:** We can talk about (*All humans are mortal*)
  - ▷ **individual things** and denote them by variables or constants
  - ▷ **properties of individuals**, (e.g. *being human or mortal*)
  - ▷ **relations of individuals**, (e.g. *sibling\_of* relationship)
  - ▷ **functions on individuals**, (e.g. the *father\_of* function)
- We can also state the **existence** of an individual with a certain property, or the **universality** of a property.
- ▷ But we cannot state assertions like
  - ▷ *There is a surjective function from the natural numbers into the reals.*
- ▷ First-Order Predicate Logic has many good properties (complete calculi, compactness, unitary, linear unification, ...)
- ▷ But too weak for formalizing: (at least directly)
  - ▷ natural numbers, torsion groups, calculus, ...
  - ▷ **generalized quantifiers** (*most, few, ...*)

### 14.2.1 First-Order Logic: Syntax and Semantics

**A Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/25094>.

The syntax and semantics of **first-order logic** is systematically organized in two distinct layers: one for **truth values** (like in **propositional logic**) and one for **individuals** (the new, distinctive feature of **first-order logic**).

The first step of defining a formal language is to specify the alphabet, here the **first-order signatures** and their components.

### $PL^1$ Syntax (Signature and Variables)

---

- ▷ **Definition 14.2.1.** **First-order logic** ( $PL^1$ ), is a **formal system** extensively used in **mathematics**, philosophy, linguistics, and **computer science**. It combines **propositional logic** with the ability to quantify over individuals.
- ▷  $PL^1$  talks about two kinds of objects: (so we have two kinds of symbols)
  - ▷ **truth values** by reusing  $PL^0$

- ▷ **individuals**, e.g. numbers, foxes, Pokémon,...
- ▷ **Definition 14.2.2.** A **first-order signature** consists of (all disjoint;  $k \in \mathbb{N}$ )
  - ▷ **connectives:**  $\Sigma_0 = \{T, F, \neg, \vee, \wedge, \Rightarrow, \Leftrightarrow, \dots\}$  (functions on truth values)
  - ▷ **function constants:**  $\Sigma_k^f = \{f, g, h, \dots\}$  ( $k$ -ary functions on individuals)
  - ▷ **predicate constants:**  $\Sigma_k^p = \{p, q, r, \dots\}$  ( $k$ -ary relations among individuals.)
  - ▷ (**Skolem constants:**  $\Sigma_k^{sk} = \{f_k^1, f_k^2, \dots\}$ ) (witness constructors; countably  $\infty$ )
  - ▷ We take  $\Sigma_1$  to be all of these together:  $\Sigma_1 := \Sigma^f \cup \Sigma^p \cup \Sigma^{sk}$  and define  $\Sigma := \Sigma_1 \cup \Sigma_0$ .
- ▷ **Definition 14.2.3.** We assume a set of **individual variables:**  $\mathcal{V}_i := \{X, Y, Z, \dots\}$ . (countably  $\infty$ )

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 409 2024-02-08

We make the deliberate, but non-standard design choice here to include Skolem constants into the signature from the start. These are used in inference systems to give names to objects and construct witnesses. Other than the fact that they are usually introduced by need, they work exactly like regular constants, which makes the inclusion rather painless. As we can never predict how many Skolem constants we are going to need, we give ourselves countably infinitely many for every arity. Our supply of individual variables is countably infinite for the same reason. The formulae of first-order logic are built up from the signature and variables as terms (to represent individuals) and propositions (to represent proposition). The latter include the connectives from  $PL^0$ , but also quantifiers.

### $PL^1$ Syntax (Formulae)

- ▷ **Definition 14.2.4. Terms:**  $A \in \text{wff}_i(\Sigma_1, \mathcal{V}_i)$  (denote individuals)
  - ▷  $\mathcal{V}_i \subseteq \text{wff}_i(\Sigma_1, \mathcal{V}_i)$ ,
  - ▷ if  $f \in \Sigma_k^f$  and  $A^i \in \text{wff}_i(\Sigma_1, \mathcal{V}_i)$  for  $i \leq k$ , then  $f(A^1, \dots, A^k) \in \text{wff}_i(\Sigma_1, \mathcal{V}_i)$ .
- ▷ **Definition 14.2.5. Propositions:**  $A \in \text{wff}_o(\Sigma_1, \mathcal{V}_i)$ : (denote truth values)
  - ▷ if  $p \in \Sigma_k^p$  and  $A^i \in \text{wff}_i(\Sigma_1, \mathcal{V}_i)$  for  $i \leq k$ , then  $p(A^1, \dots, A^k) \in \text{wff}_o(\Sigma_1, \mathcal{V}_i)$ ,
  - ▷ if  $A, B \in \text{wff}_o(\Sigma_1, \mathcal{V}_i)$  and  $X \in \mathcal{V}_i$ , then  $T, A \wedge B, \neg A, \forall X. A \in \text{wff}_o(\Sigma_1, \mathcal{V}_i)$ .  
 $\forall$  is a **binding operator** called the **universal quantifier**.
- ▷ **Definition 14.2.6.** We define the connectives  $F, \vee, \Rightarrow, \Leftrightarrow$  via the abbreviations  $A \vee B := \neg(\neg A \wedge \neg B)$ ,  $A \Rightarrow B := \neg A \vee B$ ,  $A \Leftrightarrow B := (A \Rightarrow B) \wedge (B \Rightarrow A)$ , and  $F := \neg T$ . We will use them like the primary connectives  $\wedge$  and  $\neg$
- ▷ **Definition 14.2.7.** We use  $\exists X. A$  as an abbreviation for  $\neg(\forall X. \neg A)$ .  $\exists$  is a **binding operator** called the **existential quantifier**.
- ▷ **Definition 14.2.8.** Call formulae without connectives or quantifiers **atomic** else **complex**.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 410 2024-02-08

**Note:** We only need e.g. conjunction, negation, and universal quantifier, all other logical constants can be defined from them (as we will see when we have fixed their interpreta-

tions).

### Alternative Notations for Quantifiers

| Here          | Elsewhere                  |
|---------------|----------------------------|
| $\forall x.A$ | $\bigwedge x.A \quad (x)A$ |
| $\exists x.A$ | $\bigvee x.A$              |

Michael Kohlhase: Artificial Intelligence 1
411
2024-02-08

The introduction of **quantifiers** to **first-order logic** brings a new phenomenon: **variables** that are under the scope of a **quantifiers** will behave very differently from the ones that are not. Therefore we build up a vocabulary that distinguishes the two.

### Free and Bound Variables

- ▷ **Definition 14.2.9.** We call an **occurrence** of a **variable**  $X$  **bound** in a **formula**  $A$  (otherwise **free**), iff it occurs in a **sub-formula**  $\forall X.B$  of  $A$ .  
For a **formula**  $A$ , we will use  $BVar(A)$  (and  $free(A)$ ) for the **set** of **bound** (**free**) **variables** of  $A$ , i.e. **variables** that have a **free/bound occurrence** in  $A$ .
- ▷ **Definition 14.2.10.** We define the **set**  $free(A)$  of **free variables** of a **formula**  $A$ :
 

$$\begin{aligned}
 free(X) &:= \{X\} \\
 free(f(A_1, \dots, A_n)) &:= \bigcup_{1 \leq i \leq n} free(A_i) \\
 free(p(A_1, \dots, A_n)) &:= \bigcup_{1 \leq i \leq n} free(A_i) \\
 free(\neg A) &:= free(A) \\
 free(A \wedge B) &:= free(A) \cup free(B) \\
 free(\forall X.A) &:= free(A) \setminus \{X\}
 \end{aligned}$$
- ▷ **Definition 14.2.11.** We call a **formula**  $A$  **closed** or **ground**, iff  $free(A) = \emptyset$ . We call a **closed proposition** a **sentence**, and denote the **set** of all **ground term** with  $ctff_t(\Sigma_t)$  and the **set** of **sentences** with  $ctff_o(\Sigma_t)$ .
- ▷ **Axiom 14.2.12.** **Bound variables** can be renamed, i.e. any subterm  $\forall X.B$  of a **formula**  $A$  can be replaced by  $A' := (\forall Y.B')$ , where  $B'$  arises from  $B$  by replacing all  $X \in free(B)$  with a new variable  $Y$  that does not occur in  $A$ . We call  $A'$  an **alphabetical variant** of  $A$  – and the other way around too.

Michael Kohlhase: Artificial Intelligence 1
412
2024-02-08

We will be mainly interested in (sets of) **sentences** – i.e. **closed propositions** – as the representations of **meaningful** statements about **individuals**. Indeed, we will see below that **free variables** do not gives us expressivity, since they behave like **constants** and could be replaced by them in all situations, except the **recursive** definition of quantified **formulae**. Indeed in all situations where variables occur **freely**, they have the character of meta variables, i.e. syntactic placeholders that can be instantiated with **terms** when needed in a **calculus**.

The semantics of first-order logic is a Tarski-style set-theoretic semantics where the atomic syntactic entities are interpreted by mapping them into a well-understood structure, a first-order universe that is just an arbitrary set.

### Semantics of PL<sup>1</sup> (Models)

- ▷ **Definition 14.2.13.** We inherit the domain  $\mathcal{D}_0 = \{\mathsf{T}, \mathsf{F}\}$  of truth values from  $\text{PL}^0$  and assume an arbitrary domain  $\mathcal{D}_i \neq \emptyset$  of individuals. (this choice is a parameter to the semantics)
- ▷ **Definition 14.2.14.** An interpretation  $\mathcal{I}$  assigns values to constants, e.g.
  - ▷  $\mathcal{I}(\neg): \mathcal{D}_0 \rightarrow \mathcal{D}_0$  with  $\mathsf{T} \mapsto \mathsf{F}$ ,  $\mathsf{F} \mapsto \mathsf{T}$ , and  $\mathcal{I}(\wedge) = \dots$  (as in  $\text{PL}^0$ )
  - ▷  $\mathcal{I}: \Sigma_k^f \rightarrow \mathcal{D}_i^k \rightarrow \mathcal{D}_i$  (interpret function symbols as arbitrary functions)
  - ▷  $\mathcal{I}: \Sigma_k^p \rightarrow \mathcal{P}(\mathcal{D}_i^k)$  (interpret predicates as arbitrary relations)
- ▷ **Definition 14.2.15.** A variable assignment  $\varphi: \mathcal{V}_i \rightarrow \mathcal{D}_i$  maps variables into the domain.
- ▷ **Definition 14.2.16.** A model  $\mathcal{M} = \langle \mathcal{D}_i, \mathcal{I} \rangle$  of  $\text{PL}^1$  consists of a domain  $\mathcal{D}_i$  and an interpretation  $\mathcal{I}$ .

We do not have to make the domain of truth values part of the model, since it is always the same; we determine the model by choosing a domain and an interpretation function. Given a first-order model, we can define the evaluation function as a homomorphism over the construction of formulae.

## Semantics of $\text{PL}^1$ (Evaluation)

- ▷ **Definition 14.2.17.** Given a model  $\langle \mathcal{D}, \mathcal{I} \rangle$ , the value function  $\mathcal{I}_\varphi$  is recursively defined: (two parts: terms & propositions)
  - ▷  $\mathcal{I}_\varphi: \text{wff}_i(\Sigma_1, \mathcal{V}_i) \rightarrow \mathcal{D}_i$  assigns values to terms.
    - ▷  $\mathcal{I}_\varphi(X) := \varphi(X)$  and
    - ▷  $\mathcal{I}_\varphi(f(\mathbf{A}_1, \dots, \mathbf{A}_k)) := \mathcal{I}(f)(\mathcal{I}_\varphi(\mathbf{A}_1), \dots, \mathcal{I}_\varphi(\mathbf{A}_k))$
  - ▷  $\mathcal{I}_\varphi: \text{wff}_o(\Sigma_1, \mathcal{V}_i) \rightarrow \mathcal{D}_0$  assigns values to formulae:
    - ▷  $\mathcal{I}_\varphi(\mathsf{T}) = \mathcal{I}(\mathsf{T}) = \mathsf{T}$ ,
    - ▷  $\mathcal{I}_\varphi(\neg \mathbf{A}) = \mathcal{I}(\neg)(\mathcal{I}_\varphi(\mathbf{A}))$
    - ▷  $\mathcal{I}_\varphi(\mathbf{A} \wedge \mathbf{B}) = \mathcal{I}(\wedge)(\mathcal{I}_\varphi(\mathbf{A}), \mathcal{I}_\varphi(\mathbf{B}))$  (just as in  $\text{PL}^0$ )
    - ▷  $\mathcal{I}_\varphi(p(\mathbf{A}_1, \dots, \mathbf{A}_k)) := \mathsf{T}$ , iff  $\langle \mathcal{I}_\varphi(\mathbf{A}_1), \dots, \mathcal{I}_\varphi(\mathbf{A}_k) \rangle \in \mathcal{I}(p)$
    - ▷  $\mathcal{I}_\varphi(\forall X. \mathbf{A}) := \mathsf{T}$ , iff  $\mathcal{I}_{\varphi, [a/X]}(\mathbf{A}) = \mathsf{T}$  for all  $a \in \mathcal{D}_i$ .
- ▷ **Definition 14.2.18 (Assignment Extension).** Let  $\varphi$  be a variable assignment into  $D$  and  $a \in D$ , then  $\varphi, [a/X]$  is called the extension of  $\varphi$  with  $[a/X]$  and is defined as  $\{(Y, a) \in \varphi \mid Y \neq X\} \cup \{(X, a)\}$ :  $\varphi, [a/X]$  coincides with  $\varphi$  off  $X$ , and gives the result  $a$  there.

The only new (and interesting) case in this definition is the quantifier case, there we define the value of a quantified formula by the value of its scope – but with an extension of the incoming variable assignment. Note that by passing to the scope  $\mathbf{A}$  of  $\forall x. \mathbf{A}$ , the occurrences of the variable  $x$  in  $\mathbf{A}$  that were bound in  $\forall x. \mathbf{A}$  become free and are amenable to evaluation by the variable assignment  $\psi := \varphi, [a/X]$ . Note that as an extension of  $\varphi$ , the assignment  $\psi$  supplies exactly the right value for  $x$  in  $\mathbf{A}$ . This variability of the variable assignment in the definition of the value function justifies the somewhat complex setup of first-order evaluation, where we have the (static)

interpretation function for the symbols from the signature and the (dynamic) **variable assignment** for the **variables**.

Note furthermore, that the value  $\mathcal{I}_\varphi(\exists x.\mathbf{A})$  of  $\exists x.\mathbf{A}$ , which we have defined to be  $\neg(\forall x.\neg\mathbf{A})$  is true, iff it is not the case that  $\mathcal{I}_\varphi(\forall x.\neg\mathbf{A}) = \mathcal{I}_\psi(\neg\mathbf{A}) = \mathbf{F}$  for all  $a \in \mathcal{D}_i$  and  $\psi := \varphi, [a/X]$ . This is the case, iff  $\mathcal{I}_\psi(\mathbf{A}) = \mathbf{T}$  for some  $a \in \mathcal{D}_i$ . So our definition of the existential quantifier yields the appropriate semantics.

### Semantics Computation: Example

▷ **Example 14.2.19.** We define an instance of first-order logic:

▷ **Signature:** Let  $\Sigma_0^f := \{j, m\}$ ,  $\Sigma_1^f := \{f\}$ , and  $\Sigma_2^p := \{o\}$

▷ **Universe:**  $\mathcal{D}_i := \{J, M\}$

▷ **Interpretation:**  $\mathcal{I}(j) := J$ ,  $\mathcal{I}(m) := M$ ,  $\mathcal{I}(f)(J) := M$ ,  $\mathcal{I}(f)(M) := M$ , and  $\mathcal{I}(o) := \{(M, J)\}$ .

Then  $\forall X.o(f(X), X)$  is a **sentence** and with  $\psi := \varphi, [a/X]$  for  $a \in \mathcal{D}_i$  we have

$$\begin{aligned} \mathcal{I}_\varphi(\forall X.o(f(X), X)) = \mathbf{T} & \text{ iff } \mathcal{I}_\psi(o(f(X), X)) = \mathbf{T} \text{ for all } a \in \mathcal{D}_i \\ & \text{ iff } (\mathcal{I}_\psi(f(X)), \mathcal{I}_\psi(X)) \in \mathcal{I}(o) \text{ for all } a \in \{J, M\} \\ & \text{ iff } (\mathcal{I}(f)(\mathcal{I}_\psi(X)), \psi(X)) \in \{(M, J)\} \text{ for all } a \in \{J, M\} \\ & \text{ iff } (\mathcal{I}(f)(\psi(X)), a) = (M, J) \text{ for all } a \in \{J, M\} \\ & \text{ iff } \mathcal{I}(f)(a) = M \text{ and } a = J \text{ for all } a \in \{J, M\} \end{aligned}$$

But  $a \neq J$  for  $a = M$ , so  $\mathcal{I}_\varphi(\forall X.o(f(X), X)) = \mathbf{F}$  in the model  $\langle \mathcal{D}_i, \mathcal{I} \rangle$ .

## 14.2.2 First-Order Substitutions

**A Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/25156>.

We will now turn our attention to **substitutions**, special formula-to-formula mappings that operationalize the intuition that (individual) **variables** stand for arbitrary **terms**.

### Substitutions on Terms

▷ **Intuition:** If **B** is a **term** and **X** is a **variable**, then we denote the result of systematically replacing all **occurrences** of **X** in a **term A** by **B** with  $[B/X](A)$ .

▷ **Problem:** What about  $[Z/Y], [Y/X](X)$ , is that **Y** or **Z**?

▷ **Folklore:**  $[Z/Y], [Y/X](X) = Y$ , but  $[Z/Y]([Y/X](X)) = Z$  of course.  
(Parallel application)

▷ **Definition 14.2.20.** Let  $wfe(\Sigma, \mathcal{V})$  be an **expression language**, then we call  $\sigma: \mathcal{V} \rightarrow wfe(\Sigma, \mathcal{V})$  a **substitution**, iff the **support**  $\text{supp}(\sigma) := \{X \mid (X, A) \in \sigma, X \neq A\}$  of  $\sigma$  is **finite**. We denote the **empty substitution** with  $\epsilon$ .

▷ **Definition 14.2.21.** We can **discharge** a **variable X** from a **substitution  $\sigma$**  by setting  $\sigma_{-X} := \sigma, [X/X]$ .

▷ **Definition 14.2.22 (Substitution Application).** We define **substitution application** by

- ▷  $\sigma(c) = c$  for  $c \in \Sigma$
- ▷  $\sigma(X) = \mathbf{A}$ , iff  $X \in \mathcal{V}$  and  $(X, \mathbf{A}) \in \sigma$ .
- ▷  $\sigma(f(\mathbf{A}_1, \dots, \mathbf{A}_n)) = f(\sigma(\mathbf{A}_1), \dots, \sigma(\mathbf{A}_n))$ ,
- ▷  $\sigma(\forall X. \mathbf{A}) = \forall X. \sigma_{-X}(\mathbf{A})$ . ( $\exists$  analogous)

▷ **Example 14.2.23.**  $[a/x], [f(b)/y], [a/z]$  instantiates  $g(x, y, h(z))$  to  $g(a, f(b), h(a))$ .

The extension of a [substitution](#) is an important operation, which you will run into from time to time. Given a [substitution](#)  $\sigma$ , a [variable](#)  $x$ , and an [expression](#)  $\mathbf{A}$ ,  $\sigma, [\mathbf{A}/x]$  [extends](#)  $\sigma$  with a new value for  $x$ . The intuition is that the values right of the comma overwrite the pairs in the [substitution](#) on the left, which already has a value for  $x$ , even though the representation of  $\sigma$  may not show it.

## Substitution Extension

- ▷ **Definition 14.2.24 (Substitution Extension).** Let  $\sigma$  be a [substitution](#), then we denote the [extension](#) of  $\sigma$  with  $[\mathbf{A}/X]$  by  $\sigma, [\mathbf{A}/X]$  and define it as  $\{(Y, \mathbf{B}) \in \sigma \mid Y \neq X\} \cup \{(X, \mathbf{A})\}$ :  $\sigma, [\mathbf{A}/X]$  coincides with  $\sigma$  off  $X$ , and gives the result  $\mathbf{A}$  there.
- ▷ **Note:** If  $\sigma$  is a [substitution](#), then  $\sigma, [\mathbf{A}/X]$  is also a [substitution](#).
- ▷ We also need the dual operation: removing a variable from the support:
- ▷ **Definition 14.2.25.** We can [discharge](#) a [variable](#)  $X$  from a [substitution](#)  $\sigma$  by setting  $\sigma_{-X} := \sigma, [X/X]$ .

Note that the use of the comma notation for [substitutions](#) defined in ?? is consistent with [substitution extension](#). We can view a [substitution](#)  $[a/x], [f(b)/y]$  as the extension of the [empty substitution](#) (the [identity function](#) on [variables](#)) by  $[f(b)/y]$  and then by  $[a/x]$ . Note furthermore, that [substitution extension](#) is not [commutative](#) in general.

For first-order [substitutions](#) we need to extend the [substitutions](#) defined on terms to act on propositions. This is technically more involved, since we have to take care of [bound variables](#).

## Substitutions on Propositions

- ▷ **Problem:** We want to extend [substitutions](#) to propositions, in particular to quantified formulae: What is  $\sigma(\forall X. \mathbf{A})$ ?
- ▷ **Idea:**  $\sigma$  should not instantiate [bound variables](#). ( $[\mathbf{A}/X](\forall X. \mathbf{B}) = \forall \mathbf{A}. \mathbf{B}'$  ill-formed)
- ▷ **Definition 14.2.26.**  $\sigma(\forall X. \mathbf{A}) := (\forall X. \sigma_{-X}(\mathbf{A}))$ .
- ▷ **Problem:** This can lead to [variable capture](#):  $[f(\mathbf{X})/Y](\forall X. p(X, Y))$  would evaluate to  $\forall X. p(X, f(\mathbf{X}))$ , where the second [occurrence](#) of  $\mathbf{X}$  is [bound](#) after instantiation, whereas it was [free](#) before. **Solution:** Rename away the [bound variable](#)  $X$  in  $\forall X. p(X, Y)$  before applying the [substitution](#).
- ▷ **Definition 14.2.27 (Capture-Avoiding Substitution Application).** Let  $\sigma$  be a [substitution](#),  $\mathbf{A}$  a [formula](#), and  $\mathbf{A}'$  an [alphabetic variant](#) of  $\mathbf{A}$ , such that  $\text{intro}(\sigma) \cap$

$BVar(\mathbf{A}) = \emptyset$ . Then we define **capture-avoiding substitution application** via  $\sigma(\mathbf{A}) := \sigma(\mathbf{A}')$ .

We now introduce a central tool for reasoning about the semantics of **substitutions**: the “substitution value Lemma”, which relates the process of instantiation to (semantic) evaluation. This result will be the motor of all **soundness** proofs on **axioms** and **inference rules** acting on variables via **substitutions**. In fact, any logic with **variables** and **substitutions** will have (to have) some form of a substitution value Lemma to get the meta-theory going, so it is usually the first target in any development of such a logic. We establish the substitution-value Lemma for first-order logic in two steps, first on **terms**, where it is very simple, and then on propositions.

### Substitution Value Lemma for Terms

▷ **Lemma 14.2.28.** *Let  $\mathbf{A}$  and  $\mathbf{B}$  be terms, then  $\mathcal{I}_\varphi([\mathbf{B}/X]\mathbf{A}) = \mathcal{I}_\psi(\mathbf{A})$ , where  $\psi = \varphi, [\mathcal{I}_\varphi(\mathbf{B})/X]$ .*

▷ *Proof:* by induction on the depth of  $\mathbf{A}$ :

1. depth=0 Then  $\mathbf{A}$  is a variable (say  $Y$ ), or constant, so we have three cases

1.1.  $\mathbf{A} = Y = X$

1.1.1. then  $\mathcal{I}_\varphi([\mathbf{B}/X](\mathbf{A})) = \mathcal{I}_\varphi([\mathbf{B}/X](X)) = \mathcal{I}_\varphi(\mathbf{B}) = \psi(X) = \mathcal{I}_\psi(X) = \mathcal{I}_\psi(\mathbf{A})$ .

1.2.  $\mathbf{A} = Y \neq X$

1.2.1. then  $\mathcal{I}_\varphi([\mathbf{B}/X](\mathbf{A})) = \mathcal{I}_\varphi([\mathbf{B}/X](Y)) = \mathcal{I}_\varphi(Y) = \varphi(Y) = \psi(Y) = \mathcal{I}_\psi(Y) = \mathcal{I}_\psi(\mathbf{A})$ .

1.3.  $\mathbf{A}$  is a constant

1.3.1. Analogous to the preceding case ( $Y \neq X$ ).

1.4. This completes the **base case** (depth = 0).

2. depth > 0

2.1. then  $\mathbf{A} = f(\mathbf{A}_1, \dots, \mathbf{A}_n)$  and we have

$$\begin{aligned} \mathcal{I}_\varphi([\mathbf{B}/X](\mathbf{A})) &= \mathcal{I}(f)(\mathcal{I}_\varphi([\mathbf{B}/X](\mathbf{A}_1)), \dots, \mathcal{I}_\varphi([\mathbf{B}/X](\mathbf{A}_n))) \\ &= \mathcal{I}(f)(\mathcal{I}_\psi(\mathbf{A}_1), \dots, \mathcal{I}_\psi(\mathbf{A}_n)) \\ &= \mathcal{I}_\psi(\mathbf{A}). \end{aligned}$$

by **induction hypothesis**

2.2. This completes the **induction step**, and we have proven the assertion.

### Substitution Value Lemma for Propositions

▷ **Lemma 14.2.29.**  $\mathcal{I}_\varphi([\mathbf{B}/X](\mathbf{A})) = \mathcal{I}_\psi(\mathbf{A})$ , where  $\psi = \varphi, [\mathcal{I}_\varphi(\mathbf{B})/X]$ .

▷ *Proof:* by induction on the number  $n$  of **connectives** and **quantifiers** in  $\mathbf{A}$ :

1.  $n = 0$

1.1. then  $\mathbf{A}$  is an **atomic proposition**, and we can argue like in the **induction step** of the substitution value lemma for terms.

2.  $n > 0$  and  $\mathbf{A} = \neg\mathbf{B}$  or  $\mathbf{A} = \mathbf{C} \circ \mathbf{D}$

- 2.1. Here we argue like in the **induction step** of the term lemma as well.
3.  $n > 0$  and  $\mathbf{A} = \forall Y. \mathbf{C}$  where (WLOG)  $X \neq Y$  (otherwise rename)
- 3.1. then  $\mathcal{I}_\psi(\mathbf{A}) = \mathcal{I}_\psi(\forall Y. \mathbf{C}) = \top$ , iff  $\mathcal{I}_{(\psi, [a/Y])}(\mathbf{C}) = \top$  for all  $a \in \mathcal{D}_L$ .
- 3.2. But  $\mathcal{I}_{(\psi, [a/Y])}(\mathbf{C}) = \mathcal{I}_{(\varphi, [a/Y])}([\mathbf{B}/X](\mathbf{C})) = \top$ , by **induction hypothesis**.
- 3.3. So  $\mathcal{I}_\psi(\mathbf{A}) = \mathcal{I}_\varphi(\forall Y. [\mathbf{B}/X](\mathbf{C})) = \mathcal{I}_\varphi([\mathbf{B}/X](\forall Y. \mathbf{C})) = \mathcal{I}_\varphi([\mathbf{B}/X](\mathbf{A}))$

To understand the proof fully, you should think about where the **WLOG** – it stands for **without loss of generality** comes from.

### 14.3 First-Order Natural Deduction

**A Video Nugget** covering this section can be found at <https://fau.tv/clip/id/25157>.

In this section, we will introduce the **first-order natural deduction calculus**. Recall from section 10.4 that natural deduction calculus have introduction and elimination for every **logical constant** (the **connectives** in  $\text{PL}^0$ ). Recall furthermore that we had two styles/notations for the calculus, the classical **ND calculus** and the **sequent-style** notation. These principles will be carried over to natural deduction in  $\text{PL}^1$ .

This allows us to introduce the calculi in two stages, first for the (propositional) **connectives** and then extend this to a calculus for first-order logic by adding rules for the **quantifiers**. In particular, we can define the first-order calculi simply by adding (introduction and elimination) rules for the (**universal** and **existential**) **quantifiers** to the calculus  $\mathcal{ND}_0$  defined in section 10.4.

To obtain a first-order **calculus**, we have to extend  $\mathcal{ND}_0$  with (introduction and elimination) rules for the **quantifiers**.

#### First-Order Natural Deduction ( $\mathcal{ND}^1$ ; Gentzen [Gen34])

▷ Rules for **connectives** just as always

▷ **Definition 14.3.1 (New Quantifier Rules)**. The **first-order natural deduction calculus**  $\mathcal{ND}^1$  extends  $\mathcal{ND}_0$  by the following four rules:

$$\frac{\mathbf{A}}{\forall X. \mathbf{A}} \mathcal{ND}^1 \forall I^* \qquad \frac{\forall X. \mathbf{A}}{[\mathbf{B}/X](\mathbf{A})} \mathcal{ND}^1 \forall E$$

$$\frac{[\mathbf{B}/X](\mathbf{A})}{\exists X. \mathbf{A}} \mathcal{ND}^1 \exists I \qquad \frac{\begin{array}{c} \exists X. \mathbf{A} \\ \vdots \\ \mathbf{C} \end{array} \quad \begin{array}{c} [[c/X](\mathbf{A})]^1 \\ c \in \Sigma_0^{sk} \text{ new} \end{array}}{\mathbf{C}} \mathcal{ND}^1 \exists E^1$$

\* means that  $\mathbf{A}$  does not depend on any hypothesis in which  $X$  is **free**.

The intuition behind the rule  $\mathcal{ND}^1 \forall I$  is that a formula  $\mathbf{A}$  with a (free) variable  $X$  can be generalized to  $\forall X. \mathbf{A}$ , if  $X$  stands for an arbitrary object, i.e. there are no restricting assumptions about  $X$ . The  $\mathcal{ND}^1 \forall E$  rule is just a **substitution rule** that allows to instantiate arbitrary terms  $\mathbf{B}$  for  $X$  in  $\mathbf{A}$ . The  $\mathcal{ND}^1 \exists I$  rule says if we have a witness  $\mathbf{B}$  for  $X$  in  $\mathbf{A}$  (i.e. a concrete term  $\mathbf{B}$  that makes  $\mathbf{A}$  true), then we can existentially close  $\mathbf{A}$ . The  $\mathcal{ND}^1 \exists E$  rule corresponds to the common **mathematical practice**, where we give objects we know exist a new name  $c$  and continue the proof

by reasoning about this concrete object  $c$ . Anything we can prove from the assumption  $[c/X](\mathbf{A})$  we can prove outright if  $\exists X.\mathbf{A}$  is known.

### A Complex $\mathcal{ND}^1$ Example

▷ **Example 14.3.2.** We prove  $\neg(\forall X.P(X)) \vdash_{\mathcal{ND}^1} \exists X.\neg P(X)$ .

$$\begin{array}{c}
 \frac{\frac{\frac{F}{\neg\neg P(X)} \mathcal{ND}_0\neg I^2}{\neg P(X)} \mathcal{ND}_0\neg E}{P(X)} \mathcal{ND}^1 \forall I \\
 \frac{\neg(\forall X.P(X)) \quad \forall X.P(X)}{\quad} \mathcal{ND}_0 FI \\
 \frac{F}{\neg\neg(\exists X.\neg P(X))} \mathcal{ND}_0\neg I^1 \\
 \frac{\neg\neg(\exists X.\neg P(X))}{\exists X.\neg P(X)} \mathcal{ND}_0\neg E
 \end{array}$$

$\frac{\frac{\frac{[\neg P(X)]^2}{\exists X.\neg P(X)} \mathcal{ND}^1 \exists I}{\neg(\exists X.\neg P(X))} \mathcal{ND}_0 FI}{F}$

Michael Kohlhase: Artificial Intelligence 1
422
2024-02-08

Now we reformulate the classical formulation of the [calculus of natural deduction](#) as a [sequent calculus](#) by lifting it to the “judgments level” as we did for [propositional logic](#). We only need provide new [quantifier rules](#).

### First-Order Natural Deduction in Sequent Formulation

▷ Rules for [connectives](#) from  $\mathcal{ND}_\perp^0$

▷ **Definition 14.3.3 (New Quantifier Rules).** The [inference rules](#) of the [first-order sequent calculus](#)  $\mathcal{ND}_\perp^1$  consist of those from  $\mathcal{ND}_\perp^0$  plus the following [quantifier rules](#):

$$\begin{array}{c}
 \frac{\Gamma \vdash \mathbf{A} \quad X \notin \text{free}(\Gamma)}{\Gamma \vdash \forall X.\mathbf{A}} \mathcal{ND}_\perp^1 \forall I \qquad \frac{\Gamma \vdash \forall X.\mathbf{A}}{\Gamma \vdash [\mathbf{B}/X](\mathbf{A})} \mathcal{ND}_\perp^1 \forall E \\
 \frac{\Gamma \vdash [\mathbf{B}/X](\mathbf{A})}{\Gamma \vdash \exists X.\mathbf{A}} \mathcal{ND}_\perp^1 \exists I \qquad \frac{\Gamma \vdash \exists X.\mathbf{A} \quad \Gamma, [c/X](\mathbf{A}) \vdash \mathbf{C} \quad c \in \Sigma_0^{sk} \text{ new}}{\Gamma \vdash \mathbf{C}} \mathcal{ND}_\perp^1 \exists E
 \end{array}$$

### Natural Deduction with Equality

▷ **Definition 14.3.4 (First-Order Logic with Equality).** We extend  $\text{PL}^1$  with a new [logical constant](#) for equality  $= \in \Sigma_2^p$  and fix its [interpretation](#) to  $\mathcal{I}(=) := \{(x,x) \mid x \in \mathcal{D}_i\}$ . We call the extended logic [first-order logic with equality](#) ( $\text{PL}_=^1$ )

▷ We now extend natural deduction as well.

▷ **Definition 14.3.5.** For the **calculus of natural deduction with equality** ( $\mathcal{ND}^1$ ) we add the following two **rules** to  $\mathcal{ND}^1$  to deal with equality:

$$\frac{}{A = A} =I \qquad \frac{A = B \quad C[A]_p}{[B/p]C} =E$$

where  $C[A]_p$  if the formula  $C$  has a subterm  $A$  at **position**  $p$  and  $[B/p]C$  is the result of replacing that subterm with  $B$ .

▷ In many ways **equivalence** behaves like **equality**, we will use the following rules in  $\mathcal{ND}^1$

▷ **Definition 14.3.6.**  $\Leftrightarrow I$  is **derivable** and  $\Leftrightarrow E$  is **admissible** in  $\mathcal{ND}^1$ :

$$\frac{}{A \Leftrightarrow A} \Leftrightarrow I \qquad \frac{A \Leftrightarrow B \quad C[A]_p}{[B/p]C} \Leftrightarrow E$$

Again, we have two rules that follow the introduction/elimination pattern of **natural deduction calculi**.

**Definition 14.3.7.** We have the canonical sequent rules that correspond to them:  $=I$ ,  $=E$ ,  $\Leftrightarrow I$ , and  $\Leftrightarrow E$

To make sure that we understand the constructions here, let us get back to the “replacement at position” operation used in the equality rules.

## Positions in Formulae

▷ **Idea:** Formulae are (naturally) trees, so we can use tree positions to talk about subformulae

▷ **Definition 14.3.8.** A **position**  $p$  is a **tuple of natural numbers** that in each **node** of a **expression (tree)** specifies into which **child** to descend. For a **expression**  $A$  we denote the **subexpression at  $p$**  with  $A|_p$ .

We will sometimes write a **expression**  $C$  as  $C[A]_p$  to indicate that  $C$  the **subexpression**  $A$  at **position**  $p$ .

If  $C[A]_p$  and  $A$  is **atomic**, then we speak of an **occurrence** of  $A$  in  $C$ .

▷ **Definition 14.3.9.** Let  $p$  be a **position**, then  $[A/p]C$  is the **expression** obtained from  $C$  by **replacing** the **subexpression at  $p$**  by  $A$ .

▷ **Example 14.3.10 (Schematically).**

The operation of replacing a subformula at position  $p$  is quite different from e.g. (first-order) substitutions:

- We are replacing subformulae with subformulae instead of instantiating variables with terms.
- substitutions replace all occurrences of a variable in a formula, whereas formula replacement only affects the (one) subformula at position  $p$ .

We conclude this section with an extended example: the proof of a classical mathematical result in the natural deduction calculus with equality. This shows us that we can derive strong properties about complex situations (here the real numbers; an uncountably infinite set of numbers).

$\mathcal{ND}_{=}^1$  Example:  $\sqrt{2}$  is Irrational

▷ We can do real mathematics with  $\mathcal{ND}_{=}^1$ :

▷ **Theorem 14.3.11.**  $\sqrt{2}$  is irrational

*Proof:* We prove the assertion by contradiction

1. Assume that  $\sqrt{2}$  is rational.
2. Then there are numbers  $p$  and  $q$  such that  $\sqrt{2} = p/q$ .
3. So we know  $2q^2 = p^2$ .
4. But  $2q^2$  has an odd number of prime factors while  $p^2$  an even number.
5. This is a contradiction (since they are equal), so we have proven the assertion

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 426 2024-02-08

If we want to formalize this into  $\mathcal{ND}^1$ , we have to write down all the assertions in the proof steps in  $\text{PL}^1$  syntax and come up with justifications for them in terms of  $\mathcal{ND}^1$  inference rules. The next two slides show such a proof, where we write  $m$  to denote that  $n$  is prime, use  $\#(n)$  for the number of prime factors of a number  $n$ , and write  $\text{irr}(r)$  if  $r$  is irrational.

$\mathcal{ND}_{=}^1$  Example:  $\sqrt{2}$  is Irrational (the Proof)

| #  | hyp | formula                                                                     | NDjust                              |
|----|-----|-----------------------------------------------------------------------------|-------------------------------------|
| 1  |     | $\forall n, m. \neg(2n + 1) = (2m)$                                         | lemma                               |
| 2  |     | $\forall n, m. \#(n^m) = m\#(n)$                                            | lemma                               |
| 3  |     | $\forall n, p. \text{prime}(p) \Rightarrow \#(pn) = (\#(n) + 1)$            | lemma                               |

| 6  | 6   | $\neg \text{irr}(\sqrt{2})$                                                 | $\mathcal{ND}_{=}^0 Ax$             |
| 7  | 6   | $\neg \neg(\exists p, q. \sqrt{2} = p/q)$                                   | $\Leftrightarrow E(6, 5)$           |
| 8  | 6   | $\exists p, q. \sqrt{2} = p/q$                                              | $\mathcal{ND}_{=}^0 \neg E(7)$      |
| 9  | 6,9 | $\sqrt{2} = p/q$                                                            | $\mathcal{ND}_{=}^0 Ax$             |
| 10 | 6,9 | $2q^2 = p^2$                                                                | arith(9)                            |
| 11 | 6,9 | $\#(p^2) = 2\#(p)$                                                          | $\mathcal{ND}_{=}^1 \forall E^2(2)$ |
| 12 | 6,9 | $\text{prime}(2) \Rightarrow \#(2q^2) = (\#(q^2) + 1)$                      | $\mathcal{ND}_{=}^1 \forall E^2(1)$ |

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 427 2024-02-08

Lines 6 and 9 are local hypotheses for the proof (they only have an implicit counterpart in the [inference rules](#) as defined above). Finally we have abbreviated the [arithmetic](#) simplification of line 9 with the justification “arith” to avoid having to formalize elementary [arithmetic](#).

$\mathcal{ND}^1$  Example:  $\sqrt{2}$  is Irrational (the Proof continued)

| 13 |     | prime(2)                       | lemma                                  |
|----|-----|--------------------------------|----------------------------------------|
| 14 | 6,9 | $\#(2q^2) = \#(q^2) + 1$       | $\mathcal{ND}_0 \Rightarrow E(13, 12)$ |
| 15 | 6,9 | $\#(q^2) = 2\#(q)$             | $\mathcal{ND}^1 \forall E^2(2)$        |
| 16 | 6,9 | $\#(2q^2) = 2\#(q) + 1$        | $=E(14, 15)$                           |
| 17 |     | $\#(p^2) = \#(p^2)$            | $=I$                                   |
| 18 | 6,9 | $\#(2q^2) = \#(q^2)$           | $=E(17, 10)$                           |
| 19 | 6,9 | $2\#(q) + 1 = \#(p^2)$         | $=E(18, 16)$                           |
| 20 | 6,9 | $2\#(q) + 1 = 2\#(p)$          | $=E(19, 11)$                           |
| 21 | 6,9 | $\neg(2\#(q) + 1) = (2\#(p))$  | $\mathcal{ND}^1 \forall E^2(1)$        |
| 22 | 6,9 | $F$                            | $\mathcal{ND}_0 FI(20, 21)$            |
| 23 | 6   | $F$                            | $\mathcal{ND}^1 \exists E^6(22)$       |
| 24 |     | $\neg\neg\text{irr}(\sqrt{2})$ | $\mathcal{ND}_0 \neg I^6(23)$          |
| 25 |     | $\text{irr}(\sqrt{2})$         | $\mathcal{ND}_0 \neg E^2(23)$          |

Michael Kohlhase: Artificial Intelligence 1
428
2024-02-08

We observe that the  $\mathcal{ND}^1$  proof is much more detailed, and needs quite a few Lemmata about  $\#$  to go through. Furthermore, we have added a definition of irrationality (and treat definitional equality via the equality rules). Apart from these artefacts of formalization, the two representations of proofs correspond to each other very directly.

## 14.4 Conclusion

**Summary (Predicate Logic)**

- ▷ *Predicate logic* allows to explicitly speak about objects and their properties. It is thus a more natural and compact representation language than [propositional logic](#); it also enables us to speak about [infinite](#) sets of objects.
- ▷ Logic has thousands of years of history. A major current application in [AI](#) is *Semantic Technology*.
- ▷ *First-order predicate logic (PL1)* allows *universal* and *existential quantification* over objects.
- ▷ A PL1 *interpretation* consists of a *universe  $U$*  and a function  $I$  mapping *constant symbols/predicate symbols/function symbols* to *elements/relations/functions* on  $U$ .

Michael Kohlhase: Artificial Intelligence 1

### Suggested Reading:

- *Chapter 8: First-Order Logic*, Sections 8.1 and 8.2 in [RN09]
  - A less formal account of what I cover in “Syntax” and “Semantics”. Contains different examples, and complementary explanations. Nice as additional background reading.

- Sections 8.3 and 8.4 provide additional material on using PL1, and on modeling in PL1, that I don't cover in this lecture. Nice reading, not required for exam.
- *Chapter 9: Inference in First-Order Logic*, Section 9.5.1 in [RN09]
  - A very brief (2 pages) description of what I cover in “Normal Forms”. Much less formal; I couldn't find where (if at all) RN cover transformation into prenex normal form. Can serve as additional reading, can't replace the lecture.
- **Excursion:** A full analysis of any calculus needs a completeness proof. We will not cover this in AI-1, but provide one for the calculi introduced so far in??.

# Chapter 15

## Automated Theorem Proving in First-Order Logic

In this chapter, we take up the machine-oriented calculi for propositional logic from chapter 11 and extend them to the first-order case. While this has been relatively easy for the natural deduction calculus – we only had to introduce the notion of **substitutions** for the elimination rule for the **universal quantifier** we have to work much more here to make the **calculi effective** for **implementation**.

### 15.1 First-Order Inference with Tableaux

#### 15.1.1 First-Order Tableau Calculi

A **Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/25156>.

#### Test Calculi: Tableaux and Model Generation

- ▷ **Idea:** A **tableau calculus** is a **test calculus** that
  - ▷ analyzes a **labeled formulae** in a tree to determine **satisfiability**,
  - ▷ its **branches** correspond to **valuations** ( $\rightsquigarrow$  **models**).
- ▷ **Example 15.1.1.** **Tableau calculi** try to construct models for **labeled formulae**:

| Tableau refutation (Validity)                                                                                                             | Model generation (Satisfiability)                                                                                                                                                |
|-------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\models P \wedge Q \Rightarrow Q \wedge P$                                                                                               | $\models P \wedge (Q \vee \neg R) \wedge \neg Q$                                                                                                                                 |
| $(P \wedge Q \Rightarrow Q \wedge P)^F$<br>$(P \wedge Q)^T$<br>$(Q \wedge P)^F$<br>$P^T$<br>$Q^T$<br>$P^F \mid Q^F$<br>$\perp \mid \perp$ | $(P \wedge (Q \vee \neg R) \wedge \neg Q)^T$<br>$(P \wedge (Q \vee \neg R))^T$<br>$\neg Q^T$<br>$Q^F$<br>$P^T$<br>$(Q \vee \neg R)^T$<br>$Q^T \mid \neg R^T$<br>$\perp \mid R^F$ |
| No Model                                                                                                                                  | Herbrand Model $\{P^T, Q^F, R^F\}$<br>$\varphi := \{P \mapsto T, Q \mapsto F, R \mapsto F\}$                                                                                     |

- ▷ **Idea:** Open branches in saturated tableaux yield models.

- ▷ **Algorithm:** Fully expand all possible tableaux, (no rule can be applied)
- ▷ Satisfiable, iff there are open branches (correspond to models)

Tableau calculi develop a formula in a tree-shaped arrangement that represents a case analysis on when a formula can be made true (or false). Therefore the formulae are decorated with exponents that hold the intended truth value.

On the left we have a **refutation tableau** that analyzes a negated formula (it is decorated with the intended truth value  $F$ ). Both **branches** contain an elementary contradiction  $\perp$ .

On the right we have a **model generation tableau**, which analyzes a positive formula (it is decorated with the intended truth value  $T$ ). This **tableau** uses the same rules as the refutation **tableau**, but makes a case analysis of when this formula can be satisfied. In this case we have a **closed branch** and an **open** one. The latter corresponds a model.

Now that we have seen the examples, we can write down the tableau rules formally.

### Analytical Tableaux (Formal Treatment of $\mathcal{T}_0$ )

- ▷ **Idea:** A test calculus where
  - ▷ A **labeled formula** is analyzed in a **tree** to determine **satisfiability**,
  - ▷ **branches** correspond to valuations (models)
- ▷ **Definition 15.1.2.** The **propositional tableau calculus**  $\mathcal{T}_0$  has two **inference rules** per **connective** (one for each possible label)

$$\frac{(A \wedge B)^T}{\begin{array}{l} A^T \\ B^T \end{array}} \mathcal{T}_0 \wedge \quad \frac{(A \wedge B)^F}{\begin{array}{l} A^F \\ B^F \end{array}} \mathcal{T}_0 \vee \quad \frac{\neg A^T}{A^F} \mathcal{T}_0 \neg^T \quad \frac{\neg A^F}{A^T} \mathcal{T}_0 \neg^F \quad \frac{\begin{array}{l} A^\alpha \\ A^\beta \end{array} \quad \alpha \neq \beta}{\perp} \mathcal{T}_0 \perp$$

Use rules exhaustively as long as they contribute new material ( $\rightsquigarrow$  **termination**)

- ▷ **Definition 15.1.3.** We call any **tree** ( | introduces **branches**) produced by the  $\mathcal{T}_0$  **inference rules** from a set  $\Phi$  of **labeled formulae** a **tableau** for  $\Phi$ .
- ▷ **Definition 15.1.4.** Call a **tableau** **saturated**, iff no **rule** adds new material and a **branch** **closed**, iff it ends in  $\perp$ , else **open**. A **tableau** is **closed**, iff all of its **branches** are.

These **inference rules** act on **tableaux** have to be read as follows: if the formulae over the line appear in a **tableau branch**, then the **branch** can be extended by the formulae or **branches** below the line. There are two rules for each primary **connective**, and a **branch** closing rule that adds the special symbol  $\perp$  (for unsatisfiability) to a **branch**.

We use the **tableau rules** with the convention that they are only applied, if they contribute new material to the **branch**. This ensures termination of the tableau procedure for **propositional logic** (every rule eliminates one primary **connective**).

**Definition 15.1.5.** We will call a **closed tableau** with the **labeled formula**  $A^\alpha$  at the **root** a **tableau refutation** for  $A^\alpha$ .

The **saturated tableau** represents a full case analysis of what is necessary to give **A** the truth value  $\alpha$ ; since all **branches** are **closed** (contain contradictions) this is impossible.

### Analytical Tableaux ( $\mathcal{T}_0$ continued)

---

▷ **Definition 15.1.6 ( $\mathcal{T}_0$ -Theorem/Derivability).** **A** is a  **$\mathcal{T}_0$ -theorem** ( $\vdash_{\mathcal{T}_0} \mathbf{A}$ ), iff there is a **closed tableau** with  $\mathbf{A}^F$  at the **root**.

$\Phi \subseteq \text{wff}_0(\mathcal{V}_0)$  **derives** **A** in  $\mathcal{T}_0$  ( $\Phi \vdash_{\mathcal{T}_0} \mathbf{A}$ ), iff there is a **closed tableau** starting with  $\mathbf{A}^F$  and  $\Phi^T$ . The **tableau** with only a **branch** of  $\mathbf{A}^F$  and  $\Phi^T$  is called **initial** for  $\Phi \vdash_{\mathcal{T}_0} \mathbf{A}$ .

Michael Kohlhase: Artificial Intelligence 1

2024-02-08

**Definition 15.1.7.** We will call a **tableau refutation** for  $\mathbf{A}^F$  a **tableau proof** for **A**, since it refutes the possibility of finding a model where **A** evaluates to **F**. Thus **A** must evaluate to **T** in all models, which is just our definition of validity.

Thus the tableau procedure can be used as a calculus for **propositional logic**. In contrast to the propositional Hilbert calculus it does not prove a theorem **A** by deriving it from a set of axioms, but it proves it by refuting its negation. Such calculi are called **negative** or **test calculi**. Generally negative calculi have computational advantages over positive ones, since they have a built-in sense of direction.

We have rules for all the necessary **connectives** (we restrict ourselves to  $\wedge$  and  $\neg$ , since the others can be expressed in terms of these two via the propositional identities above. For instance, we can write  $\mathbf{A} \vee \mathbf{B}$  as  $\neg(\neg\mathbf{A} \wedge \neg\mathbf{B})$ , and  $\mathbf{A} \Rightarrow \mathbf{B}$  as  $\neg\mathbf{A} \vee \mathbf{B}, \dots$ )

We will now extend the propositional tableau techniques to **first-order logic**. We only have to add two new rules for the **universal quantifier** (in **positive** and **negative** polarity).

### First-Order Standard Tableaux ( $\mathcal{T}_1$ )

---

▷ **Definition 15.1.8.** The **standard tableau calculus** ( $\mathcal{T}_1$ ) extends  $\mathcal{T}_0$  (**propositional tableau calculus**) with the following **quantifier** rules:

$$\frac{(\forall X.\mathbf{A})^T \quad \mathbf{C} \in \text{cwff}_\iota(\Sigma_\iota)}{([\mathbf{C}/X](\mathbf{A}))^T} \mathcal{T}_1 \forall \qquad \frac{(\forall X.\mathbf{A})^F \quad c \in \Sigma_0^{sk} \text{ new}}{([c/X](\mathbf{A}))^F} \mathcal{T}_1 \exists$$

▷ **Problem:** The rule  $\mathcal{T}_1 \forall$  displays a case of “don’t know indeterminism”: to find a **refutation** we have to guess a formula **C** from the (usually **infinite**) set  $\text{cwff}_\iota(\Sigma_\iota)$ . For proof search, this means that we have to systematically try all, so  $\mathcal{T}_1 \forall$  is **infinitely** branching in general.

Michael Kohlhase: Artificial Intelligence 1
433
2024-02-08

The rule  $\mathcal{T}_1 \forall$  operationalizes the intuition that a universally quantified formula is true, iff all of the instances of the scope are. To understand the  $\mathcal{T}_1 \exists$  rule, we have to keep in mind that  $\exists X.\mathbf{A}$  abbreviates  $\neg(\forall X.\neg\mathbf{A})$ , so that we have to read  $(\forall X.\mathbf{A})^F$  existentially — i.e. as  $(\exists X.\neg\mathbf{A})^T$ , stating that there is an object with property  $\neg\mathbf{A}$ . In this situation, we can simply give this object a name:  $c$ , which we take from our (infinite) set of witness constants  $\Sigma_0^{sk}$ , which we have given ourselves expressly for this purpose when we defined first-order syntax. In other words  $([c/X](\neg\mathbf{A}))^T = ([c/X](\mathbf{A}))^F$  holds, and this is just the conclusion of the  $\mathcal{T}_1 \exists$  rule.

Note that the  $\mathcal{T}_1 \forall$  rule is computationally extremely inefficient: we have to guess an (i.e. in a search setting to systematically consider all) instance  $\mathbf{C} \in \text{wff}_\iota(\Sigma_\iota, \mathcal{V}_\iota)$  for  $X$ . This makes the rule **infinitely** branching.

In the next calculus we will try to remedy the computational inefficiency of the  $\mathcal{T}_1^f \forall$  rule. We do this by delaying the choice in the universal rule.

## Free variable Tableaux ( $\mathcal{T}_1^f$ )

▷ **Definition 15.1.9.** The **free variable tableau calculus** ( $\mathcal{T}_1^f$ ) extends  $\mathcal{T}_0$  (propositional tableau calculus) with the **quantifier rules**:

$$\frac{(\forall X.\mathbf{A})^T \quad Y \text{ new}}{([Y/X](\mathbf{A}))^T} \mathcal{T}_1^f \forall \quad \frac{(\forall X.\mathbf{A})^F \quad \text{free}(\forall X.\mathbf{A}) = \{X^1, \dots, X^k\} \quad f \in \Sigma_k^{sk} \text{ new}}{([f(X^1, \dots, X^k)/X](\mathbf{A}))^F} \mathcal{T}_1^f \exists$$

and generalizes its cut rule  $\mathcal{T}_0 \perp$  to:

$$\frac{\mathbf{A}^\alpha \quad \mathbf{B}^\beta \quad \alpha \neq \beta \quad \sigma(\mathbf{A}) = \sigma(\mathbf{B})}{\perp : \sigma} \mathcal{T}_1^f \perp$$

$\mathcal{T}_1^f \perp$  instantiates the whole tableau by  $\sigma$ .

▷ **Advantage:** No guessing necessary in  $\mathcal{T}_1^f \forall$ -rule!

▷ **New Problem:** find suitable substitution (most general unifier) (later)

**Metavariables:** Instead of guessing a concrete instance for the universally quantified variable as in the  $\mathcal{T}_1 \forall$  rule,  $\mathcal{T}_1^f \forall$  instantiates it with a new meta-variable  $Y$ , which will be instantiated by need in the course of the derivation.

**Skolem terms as witnesses:** The introduction of meta-variables makes is necessary to extend the treatment of witnesses in the existential rule. Intuitively, we cannot simply invent a new name, since the **meaning** of the body  $\mathbf{A}$  may contain meta-variables introduced by the  $\mathcal{T}_1^f \forall$  rule. As we do not know their values yet, the witness for the existential statement in the antecedent of the  $\mathcal{T}_1^f \exists$  rule needs to depend on that. So witness it using a witness term, concretely by applying a Skolem function to the meta-variables in  $\mathbf{A}$ .

**Instantiating Metavariables:** Finally, the  $\mathcal{T}_1^f \perp$  rule completes the treatment of meta-variables, it allows to instantiate the whole tableau in a way that the current branch closes. This leaves us with the problem of finding **substitutions** that make two terms equal.

## Free variable Tableaux ( $\mathcal{T}_1^f$ ): Derivable Rules

▷ **Definition 15.1.10.** Derivable quantifier rules in  $\mathcal{T}_1^f$ :

$$\frac{(\exists X.\mathbf{A})^T \quad \text{free}(\forall X.\mathbf{A}) = \{X^1, \dots, X^k\} \quad f \in \Sigma_k^{sk} \text{ new}}{([f(X^1, \dots, X^k)/X](\mathbf{A}))^T} \quad \frac{(\exists X.\mathbf{A})^F \quad Y \text{ new}}{([Y/X](\mathbf{A}))^F}$$

### Tableau Reasons about Blocks

▷ **Example 15.1.11 (Reasoning about Blocks).** Returning to slide 400

Can we prove  $\text{red}(\mathbf{A})$  from  $\forall x.\text{block}(x) \Rightarrow \text{red}(x)$  and  $\text{block}(\mathbf{A})$ ?

$$\begin{array}{c}
 (\forall X.\text{block}(X) \Rightarrow \text{red}(X))^T \\
 \text{block}(\mathbf{A})^T \\
 \text{red}(\mathbf{A})^F \\
 (\text{block}(Y) \Rightarrow \text{red}(Y))^T \\
 \text{block}(Y)^F \mid \text{red}(\mathbf{A})^T \\
 \perp : [\mathbf{A}/Y] \quad \mid \quad \perp
 \end{array}$$

## 15.1.2 First-Order Unification

**Video Nuggets** covering this subsection can be found at <https://fau.tv/clip/id/26810> and <https://fau.tv/clip/id/26811>.

We will now look into the problem of finding a **substitution**  $\sigma$  that make two **terms** equal (we say it unifies them) in more detail. The presentation of the **unification algorithm** we give here “transformation-based” this has been a very influential way to treat certain **algorithms** in theoretical computer science.

**A transformation-based view of algorithms:** The “transformation-based” view of **algorithms** divides two concerns in presenting and reasoning about **algorithms** according to Kowalski’s slogan [Kow97]

algorithm = logic + control

The computational paradigm highlighted by this quote is that (many) **algorithms** can be thought of as manipulating representations of the problem at hand and transforming them into a form that makes it simple to read off solutions. Given this, we can simplify thinking and reasoning about such **algorithms** by separating out their “logical” part, which deals with is concerned with how the problem representations can be manipulated in principle from the “control” part, which is concerned with questions about when to apply which transformations.

It turns out that many questions about the **algorithms** can already be answered on the “logic” level, and that the “logical” analysis of the **algorithm** can already give strong hints as to how to optimize control.

In fact we will only concern ourselves with the “logical” analysis of **unification** here.

The first step towards a theory of unification is to take a closer look at the problem itself. A first set of examples show that we have multiple solutions to the problem of finding **substitutions** that make two **terms** equal. But we also see that these are related in a systematic way.

### Unification (Definitions)

▷ **Definition 15.1.12.** For given **terms**  $\mathbf{A}$  and  $\mathbf{B}$ , **unification** is the problem of finding a **substitution**  $\sigma$ , such that  $\sigma(\mathbf{A}) = \sigma(\mathbf{B})$ .

▷ **Notation:** We write **term pairs** as  $\mathbf{A}=?\mathbf{B}$  e.g.  $f(X)=?f(g(Y))$ .

- ▷ **Definition 15.1.13.** Solutions (e.g.  $[g(a)/X], [a/Y], [g(g(a))/X], [g(a)/Y]$ , or  $[g(Z)/X], [Z/Y]$ ) are called **unifiers**,  $\mathbf{U}(\mathbf{A}=?\mathbf{B}) := \{\sigma \mid \sigma(\mathbf{A}) = \sigma(\mathbf{B})\}$ .
- ▷ **Idea:** Find representatives in  $\mathbf{U}(\mathbf{A}=?\mathbf{B})$ , that generate the set of solutions.
- ▷ **Definition 15.1.14.** Let  $\sigma$  and  $\theta$  be **substitutions** and  $W \subseteq \mathcal{V}_i$ , we say that a **substitution**  $\sigma$  is **more general** than  $\theta$  (on  $W$ ; write  $\sigma \leq \theta[W]$ ), iff there is a **substitution**  $\rho$ , such that  $\theta = (\rho \circ \sigma)[W]$ , where  $\sigma = \rho[W]$ , iff  $\sigma(X) = \rho(X)$  for all  $X \in W$ .
- ▷ **Definition 15.1.15.**  $\sigma$  is called a **most general unifier (mgu)** of  $\mathbf{A}$  and  $\mathbf{B}$ , iff it is **minimal** in  $\mathbf{U}(\mathbf{A}=?\mathbf{B})$  wrt.  $\leq[(\text{free}(\mathbf{A}) \cup \text{free}(\mathbf{B}))]$ .

The idea behind a **most general unifier** is that all other **unifiers** can be obtained from it by (further) instantiation. In an automated theorem proving setting, this means that using **most general unifiers** is the least committed choice — any other choice of **unifiers** (that would be necessary for completeness) can later be obtained by other **substitutions**.

Note that there is a subtlety in the definition of the ordering on **substitutions**: we only compare on a subset of the **variables**. The reason for this is that we have defined **substitutions** to be total on (the **infinite** set of) **variables** for flexibility, but in the applications (see the definition of **most general unifiers**), we are only interested in a subset of variables: the ones that occur in the initial problem formulation. Intuitively, we do not care what the **unifiers** do off that set. If we did not have the restriction to the set  $W$  of variables, the ordering relation on **substitutions** would become much too fine-grained to be useful (i.e. to guarantee unique **most general unifiers** in our case).

Now that we have defined the problem, we can turn to the **unification algorithm** itself. We will define it in a way that is very similar to **logic programming**: we first define a calculus that generates “solved forms” (formulae from which we can read off the solution) and reason about control later. In this case we will reason that control does not matter.

## Unification Problems ( $\hat{=}$ Equational Systems)

- ▷ **Idea:** Unification is equation solving.
- ▷ **Definition 15.1.16.** We call a formula  $\mathbf{A}^1=?\mathbf{B}^1 \wedge \dots \wedge \mathbf{A}^n=?\mathbf{B}^n$  an **unification problem** iff  $\mathbf{A}^i, \mathbf{B}^i \in \text{wff}_i(\Sigma_i, \mathcal{V}_i)$ .
- ▷ **Note:** We consider **unification problems** as sets of equations ( $\wedge$  is **ACI**), and equations as two-element **multisets** ( $=?$  is **C**).
- ▷ **Definition 15.1.17.** A **substitution** is called a **unifier** for a **unification problem**  $\mathcal{E}$  (and thus  $\mathcal{D}$  **unifiable**), iff it is a (simultaneous) **unifier** for all **pairs** in  $\mathcal{E}$ .

In principle, **unification problems** are sets of equations, which we write as **conjunctions**, since all of them have to be solved for finding a **unifier**. Note that it is not a problem for the “logical view” that the representation as conjunctions induces an order, since we know that conjunction is associative, commutative and idempotent, i.e. that conjuncts do not have an intrinsic order or multiplicity, if we consider two equational problems as equal, if they are equivalent as propositional formulae. In the same way, we will abstract from the order in equations, since we know that the equality relation is **symmetric**. Of course we would have to deal with this somehow in the **implementation** (typically, we would **implement** equational problems as lists of **pairs**), but that belongs into the “control” aspect of the **algorithm**, which we are abstracting from at the moment.

## Solved forms and Most General Unifiers

- ▷ **Definition 15.1.18.** We call a pair  $\mathbf{A}=?\mathbf{B}$  **solved** in a unification problem  $\mathcal{E}$ , iff  $\mathbf{A} = X$ ,  $\mathcal{E} = X=?\mathbf{A} \wedge \mathcal{E}$ , and  $X \notin (\text{free}(\mathbf{A}) \cup \text{free}(\mathcal{E}))$ . We call an unification problem  $\mathcal{E}$  a **solved form**, iff all its pairs are solved.
- ▷ **Lemma 15.1.19.** Solved forms are of the form  $X^1=?\mathbf{B}^1 \wedge \dots \wedge X^n=?\mathbf{B}^n$  where the  $X^i$  are distinct and  $X^i \notin \text{free}(\mathbf{B}^j)$ .
- ▷ **Definition 15.1.20.** Any substitution  $\sigma = [\mathbf{B}^1/X^1], \dots, [\mathbf{B}^n/X^n]$  induces a solved unification problem  $\mathcal{E}_\sigma := (X^1=?\mathbf{B}^1 \wedge \dots \wedge X^n=?\mathbf{B}^n)$ .
- ▷ **Lemma 15.1.21.** If  $\mathcal{E} = X^1=?\mathbf{B}^1 \wedge \dots \wedge X^n=?\mathbf{B}^n$  is a solved form, then  $\mathcal{E}$  has the unique most general unifier  $\sigma_\mathcal{E} := [\mathbf{B}^1/X^1], \dots, [\mathbf{B}^n/X^n]$ .
- ▷ **Proof:** Let  $\theta \in \mathbf{U}(\mathcal{E})$ 
  1. then  $\theta(X^i) = \theta(\mathbf{B}^i) = \theta \circ \sigma_\mathcal{E}(X^i)$
  2. and thus  $\theta = (\theta \circ \sigma_\mathcal{E})[\text{supp}(\sigma)]$ .
- ▷ **Note:** We can rename the introduced variables in most general unifiers!

It is essential to our “logical” analysis of the **unification algorithm** that we arrive at **unification problems** whose **unifiers** we can read off easily. **Solved forms** serve that need perfectly as Lemma 15.1.21 shows.

Given the idea that **unification problems** can be expressed as formulae, we can express the **algorithm** in three simple rules that transform **unification problems** into **solved forms** (or unsolvable ones).

## Unification Algorithm

- ▷ **Definition 15.1.22.** The inference system  $\mathcal{U}$  consists of the following rules:

$$\frac{\mathcal{E} \wedge f(\mathbf{A}^1, \dots, \mathbf{A}^n) = ? f(\mathbf{B}^1, \dots, \mathbf{B}^n)}{\mathcal{E} \wedge \mathbf{A}^1 = ? \mathbf{B}^1 \wedge \dots \wedge \mathbf{A}^n = ? \mathbf{B}^n} \mathcal{U}_{\text{dec}} \qquad \frac{\mathcal{E} \wedge \mathbf{A} = ? \mathbf{A}}{\mathcal{E}} \mathcal{U}_{\text{triv}}$$

$$\frac{\mathcal{E} \wedge X = ? \mathbf{A} \quad X \notin \text{free}(\mathbf{A}) \quad X \in \text{free}(\mathcal{E})}{[\mathbf{A}/X](\mathcal{E}) \wedge X = ? \mathbf{A}} \mathcal{U}_{\text{elim}}$$

- ▷ **Lemma 15.1.23.**  $\mathcal{U}$  is **correct**:  $\mathcal{E} \vdash_{\mathcal{U}} \mathcal{F}$  implies  $\mathbf{U}(\mathcal{F}) \subseteq \mathbf{U}(\mathcal{E})$ .
- ▷ **Lemma 15.1.24.**  $\mathcal{U}$  is **complete**:  $\mathcal{E} \vdash_{\mathcal{U}} \mathcal{F}$  implies  $\mathbf{U}(\mathcal{E}) \subseteq \mathbf{U}(\mathcal{F})$ .
- ▷ **Lemma 15.1.25.**  $\mathcal{U}$  is **confluent**: the order of derivations does not matter.
- ▷ **Corollary 15.1.26.** First-order unification is **unitary**: i.e. most general unifiers are unique up to renaming of introduced variables.
- ▷ **Proof sketch:**  $\mathcal{U}$  is trivially branching.

The decomposition rule  $\mathcal{U}_{\text{dec}}$  is completely straightforward, but note that it transforms one **unification pair** into multiple argument **pairs**; this is the reason, why we have to directly use **unification**

problems with multiple pairs in  $\mathcal{U}$ .

Note furthermore, that we could have restricted the  $\mathcal{U}_{\text{triv}}$  rule to variable-variable pairs, since for any other pair, we can decompose until only variables are left. Here we observe, that constant-constant pairs can be decomposed with the  $\mathcal{U}_{\text{dec}}$  rule in the somewhat degenerate case without arguments.

Finally, we observe that the first of the two variable conditions in  $\mathcal{U}_{\text{elim}}$  (the “occurs-in-check”) makes sure that we only apply the transformation to unifiable unification problems, whereas the second one is a termination condition that prevents the rule to be applied twice.

The notion of completeness and correctness is a bit different than that for calculi that we compare to the entailment relation. We can think of the “logical system of unifiability” with the model class of sets of substitutions, where a set satisfies an equational problem  $\mathcal{E}$ , iff all of its members are unifiers. This view induces the soundness and completeness notions presented above.

The three meta-properties above are relatively trivial, but somewhat tedious to prove, so we leave the proofs as an exercise to the reader.

We now fortify our intuition about the unification calculus by two examples. Note that we only need to pursue one possible  $\mathcal{U}$  derivation since we have confluence.

### Unification Examples

▷ **Example 15.1.27.** Two similar unification problems:

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

2024-02-08

We will now convince ourselves that there cannot be any infinite sequences of transformations in  $\mathcal{U}$ . Termination is an important property for an algorithm.

The proof we present here is very typical for termination proofs. We map unification problems into a partially ordered set  $\langle S, \prec \rangle$  where we know that there cannot be any infinitely descending sequences (we think of this as measuring the unification problems). Then we show that all transformations in  $\mathcal{U}$  strictly decrease the measure of the unification problems and argue that if there were an infinite transformation in  $\mathcal{U}$ , then there would be an infinite descending chain in  $S$ , which contradicts our choice of  $\langle S, \prec \rangle$ .

The crucial step in coming up with such proofs is finding the right partially ordered set. Fortunately, there are some tools we can make use of. We know that  $\langle \mathbb{N}, < \rangle$  is terminating, and there are some ways of lifting component orderings to complex structures. For instance it is well-known that the lexicographic ordering lifts a terminating ordering to a terminating ordering on finite dimensional Cartesian spaces. We show a similar, but less known construction with multisets for our proof.

## Unification (Termination)

- ▷ **Definition 15.1.28.** Let  $S$  and  $T$  be multisets and  $\leq$  a partial ordering on  $S \cup T$ . Then we define  $S \prec^m T$ , iff  $S = C \uplus T'$  and  $T = C \uplus \{t\}$ , where  $s \leq t$  for all  $s \in S'$ . We call  $\leq^m$  the multiset ordering induced by  $\leq$ .
- ▷ **Definition 15.1.29.** We call a variable  $X$  solved in an unification problem  $\mathcal{E}$ , iff  $\mathcal{E}$  contains a solved pair  $X = ?\mathbf{A}$ .
- ▷ **Lemma 15.1.30.** If  $\prec$  is linear/terminating on  $S$ , then  $\prec^m$  is linear/terminating on  $\mathcal{P}(S)$ .
- ▷ **Lemma 15.1.31.**  $\mathcal{U}$  is terminating. (any  $\mathcal{U}$ -derivation is finite)
- ▷ **Proof:** We prove termination by mapping  $\mathcal{U}$  transformation into a Noetherian space.
  1. Let  $\mu(\mathcal{E}) := \langle n, \mathcal{N} \rangle$ , where
    - ▷  $n$  is the number of unsolved variables in  $\mathcal{E}$
    - ▷  $\mathcal{N}$  is the multiset of term depths in  $\mathcal{E}$
  2. The lexicographic order  $\prec$  on pairs  $\mu(\mathcal{E})$  is decreased by all inference rules.
    - 2.1.  $\mathcal{U}_{\text{dec}}$  and  $\mathcal{U}_{\text{triv}}$  decrease the multiset of term depths without increasing the unsolved variables.
    - 2.2.  $\mathcal{U}_{\text{elim}}$  decreases the number of unsolved variables (by one), but may increase term depths.

But it is very simple to create terminating calculi, e.g. by having no inference rules. So there is one more step to go to turn the termination result into a decidability result: we must make sure that we have enough inference rules so that any unification problem is transformed into solved form if it is unifiable.

## First-Order Unification is Decidable

- ▷ **Definition 15.1.32.** We call an equational problem  $\mathcal{E}$   $\mathcal{U}$ -reducible, iff there is a  $\mathcal{U}$ -step  $\mathcal{E} \vdash_{\mathcal{U}} \mathcal{F}$  from  $\mathcal{E}$ .
  - ▷ **Lemma 15.1.33.** If  $\mathcal{E}$  is unifiable but not solved, then it is  $\mathcal{U}$ -reducible.
  - ▷ **Proof:** We assume that  $\mathcal{E}$  is unifiable but unsolved and show the  $\mathcal{U}$  rule that applies.
    1. There is an unsolved pair  $\mathbf{A} = ?\mathbf{B}$  in  $\mathcal{E} = \mathcal{E} \wedge \mathbf{A} = ?\mathbf{B}$ .  
we have two cases
    2.  $\mathbf{A}, \mathbf{B} \notin \mathcal{V}_i$ 
      - 2.1. then  $\mathbf{A} = f(\mathbf{A}^1 \dots \mathbf{A}^n)$  and  $\mathbf{B} = f(\mathbf{B}^1 \dots \mathbf{B}^n)$ , and thus  $\mathcal{U}_{\text{dec}}$  is applicable
    3.  $\mathbf{A} = X \in \text{free}(\mathcal{E})$ 
      - 3.1. then  $\mathcal{U}_{\text{elim}}$  (if  $\mathbf{B} \neq X$ ) or  $\mathcal{U}_{\text{triv}}$  (if  $\mathbf{B} = X$ ) is applicable.
  - ▷ **Corollary 15.1.34.** First-order unification is decidable in  $\text{P}^1$ .
- Proof:*
- ▷ 1.  $\mathcal{U}$ -irreducible unification problems can be reached in finite time by Lemma 15.1.31
  - ▷ 2. They are either solved or unsolvable by Lemma 15.1.33, so they provide the answer.

### 15.1.3 Efficient Unification

Now that we have seen the basic ingredients of an [unification algorithm](#), let us as always consider [complexity](#) and [efficiency](#) issues.

We start with a look at the [complexity](#) of unification and – somewhat surprisingly – find [exponential time/space complexity](#) based simply on the fact that the results – the [unifiers](#) – can be exponentially large.

#### Complexity of Unification

▷ **Observation:** Naive [implementations](#) of unification are exponential in time and space.

▷ **Example 15.1.35.** Consider the terms

$$\begin{aligned} s_n &= f(f(x_0, x_0), f(f(x_1, x_1), f(\dots, f(x_{n-1}, x_{n-1})))) \\ t_n &= f(x_1, f(x_2, f(x_3, f(\dots, x_n)))) \end{aligned}$$

▷ The [most general unifier](#) of  $s_n$  and  $t_n$  is

$$\sigma_n := [f(x_0, x_0)/x_1, [f(f(x_0, x_0), f(x_0, x_0))/x_2, [f(f(f(x_0, x_0), f(x_0, x_0)), f(f(x_0, x_0), f(x_0, x_0)))/x_3], \dots$$

▷ It contains  $\sum_{i=1}^n 2^i = 2^{n+1} - 2$  [occurrences](#) of the variable  $x_0$ . ([exponential](#))

▷ **Problem:** The variable  $x_0$  has been copied too often.

▷ **Idea:** Find a term representation that re-uses subterms.

Indeed, the only way to escape this [combinatorial explosion](#) is to find representations of [substitutions](#) that are more space [efficient](#).

#### Directed Acyclic Graphs (DAGs) for Terms

▷ **Recall:** Terms in first-order logic are essentially [trees](#).

▷ **Concrete Idea:** Use [directed acyclic graphs](#) for representing [terms](#):

▷ variables may only occur once in the [DAG](#).

▷ subterms can be referenced multiply. ([subterm sharing](#))

▷ we can even represent multiple terms in a common [DAG](#)

▷ **Observation 15.1.36.** *Terms can be transformed into DAGs in linear time.*

▷ **Example 15.1.37.** Continuing from Example 15.1.35 ...  $s_3$ ,  $t_3$ , and  $\sigma_3(s_3)$  as [DAGs](#):

In general:  $s_n, t_n,$  and  $\sigma_n(s_n)$  only need space in  $\mathcal{O}(n)$ . (just count)

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 445 2024-02-08

If we look at the [unification algorithm](#) from Definition 15.1.22 and the considerations in the termination proof (Lemma 442) with a particular focus on the role of copying, we easily find the culprit for the exponential blowup:  $\mathcal{U}_{elim}$ , which applies [solved pairs](#) as [substitutions](#).

### DAG Unification Algorithm

- ▷ **Observation:** In  $\mathcal{U}$ , the  $\mathcal{U}_{elim}$  rule applies [solved pairs](#)  $\rightsquigarrow$  subterm duplication.
- ▷ **Idea:** Replace  $\mathcal{U}_{elim}$  the notion of [solved forms](#) by something better.
- ▷ **Definition 15.1.38.** We say that  $X^1=?B^1 \wedge \dots \wedge X^n=?B^n$  is a **DAG solved form**, iff the  $X^i$  are distinct and  $X^i \notin \text{free}(B^j)$  for  $i \leq j$ .
- ▷ **Definition 15.1.39.** The inference system  $\mathcal{DU}$  contains rules  $\mathcal{U}_{dec}$  and  $\mathcal{U}_{triv}$  from  $\mathcal{U}$  plus the following:
 
$$\frac{\mathcal{E} \wedge X=?A \wedge X=?B \quad A, B \notin \mathcal{V}_i \quad |A| \leq |B|}{\mathcal{E} \wedge X=?A \wedge A=?B} \mathcal{DU}_{merge}$$

$$\frac{\mathcal{E} \wedge X=?Y \quad X \neq Y \quad X, Y \in \text{free}(\mathcal{E})}{[Y/X](\mathcal{E}) \wedge X=?Y} \mathcal{DU}_{evar}$$
 where  $|A|$  is the number of symbols in  $A$ .
- ▷ The analysis for  $\mathcal{U}$  applies mutatis mutandis.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 446 2024-02-08

We will now turn the ideas we have developed in the last couple of slides into a usable functional [algorithm](#). The starting point is treating [terms](#) as [DAGs](#). Then we try to conduct the transformation into [solved form](#) without adding new nodes.

### Unification by DAG-chase

- ▷ **Idea:** Extend the Input-DAGs by [edges](#) that represent [unifiers](#).
- ▷ **Definition 15.1.40.** Write  $n.a$ , if  $a$  is the symbol of node  $n$ .
- ▷ (standard) auxiliary procedures: (all constant or linear time in DAGs)
  - ▷  $\text{find}(n)$  follows the path from  $n$  and returns the end node.

- ▷  $\text{union}(n, m)$  adds an edge between  $n$  and  $m$ .
- ▷  $\text{occur}(n, m)$  determines whether  $n.x$  occurs in the DAG with root  $m$ .

## Algorithm dag-unify

- ▷ Input: symmetric pairs of nodes in DAGs

```

fun dag-unify(n, n) = true
 | dag-unify($n.x, m$) = if occur(n, m) then true else union(n, m)
 | dag-unify($n.f, m.g$) =
 if $g \neq f$ then false
 else
 forall (i, j) => dag-unify(find(i), find(j)) (chld m , chld n)
end

```

- ▷ **Observation 15.1.41.**  $\text{dag-unify}$  uses *linear space*, since no new nodes are created, and at most one link per variable.
- ▷ **Problem:**  $\text{dag-unify}$  still uses exponential time.
- ▷ **Example 15.1.42.** Consider terms  $f(s_n, f(t'_n, x_n)), f(t_n, f(s'_n, y_n))$ , where  $s'_n = [y_i/x_i](s_n)$  und  $t'_n = [y_i/x_i](t_n)$ .  
 $\text{dag-unify}$  needs exponentially many recursive calls to unify the nodes  $x_n$  and  $y_n$ .  
 (they are unified after  $n$  calls, but checking needs the time)

## Algorithm uf-unify

- ▷ **Recall:**  $\text{dag-unify}$  still uses exponential time.
- ▷ **Idea:** Also bind the function nodes, if the arguments are unified.

```

uf-unify($n.f, m.g$) =
 if $g \neq f$ then false
 else union(n, m);
 forall (i, j) => uf-unify(find(i), find(j)) (chld m , chld n)
end

```

- ▷ This only needs linearly many recursive calls as it directly returns with true or makes a node inaccessible for find.
- ▷ Linearly many calls to linear procedures give quadratic *running time*.
- ▷ **Remark:** There are versions of  $\text{uf-unify}$  that are linear in time and space, but for most purposes, our algorithm suffices.

### 15.1.4 Implementing First-Order Tableaux

A **Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/26797>.

We now come to some issues (and clarifications) pertaining to **implementing** proof search for free variable tableaux. They all have to do with the – often overlooked – fact that  $\mathcal{T}_1^f \perp$  instantiates the whole tableau.

The first question one may ask for **implementation** is whether we expect a terminating proof search; after all,  $\mathcal{T}_0$  terminated. We will see that the situation for  $\mathcal{T}_1^f$  is different.

#### Termination and Multiplicity in Tableaux

- ▷ **Recall:** In  $\mathcal{T}_0$ , all rules only needed to be applied once.  
 $\sim \mathcal{T}_0$  terminates and thus induces a **decision procedure** for  $PL^0$ .
- ▷ **Observation 15.1.43.** All  $\mathcal{T}_1^f$  rules except  $\mathcal{T}_1^f \forall$  only need to be applied once.
- ▷ **Example 15.1.44.** A tableau proof for  $(p(a) \vee p(b)) \Rightarrow (\exists x.p(x))$ .

| Start, close left branch                                                                                                                                                                                                         | use $\mathcal{T}_1^f \forall$ again (right branch)                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $\begin{array}{l} ((p(a) \vee p(b)) \Rightarrow (\exists x.p(x)))^F \\ (p(a) \vee p(b))^T \\ (\exists x.p(x))^F \\ (\forall x.\neg p(x))^T \\ \neg p(y)^T \\ p(y)^F \\ p(a)^T \quad   \quad p(b)^T \\ \perp : [a/y] \end{array}$ | $\begin{array}{l} ((p(a) \vee p(b)) \Rightarrow (\exists x.p(x)))^F \\ (p(a) \vee p(b))^T \\ (\exists x.p(x))^F \\ (\forall x.\neg p(x))^T \\ \neg p(a)^T \\ p(a)^F \\ p(a)^T \quad   \quad p(b)^T \\ \perp : [a/y] \quad   \quad \neg p(z)^T \\ \quad \quad \quad \quad   \quad p(z)^F \\ \quad \quad \quad \quad   \quad \perp : [b/z] \end{array}$ |

After we have used up  $p(y)^F$  by applying  $[a/y]$  in  $\mathcal{T}_1^f \perp$ , we have to get a new instance  $p(z)^F$  via  $\mathcal{T}_1^f \forall$ .

- ▷ **Definition 15.1.45.** Let  $\mathcal{T}$  be a **tableau** for  $\mathbf{A}$ , and a positive **occurrence** of  $\forall x.\mathbf{B}$  in  $\mathbf{A}$ , then we call the number of applications of  $\mathcal{T}_1^f \forall$  to  $\forall x.\mathbf{B}$  its **multiplicity**.
- ▷ **Observation 15.1.46.** Given a prescribed **multiplicity** for each positive  $\forall$ , **saturation** with  $\mathcal{T}_1^f$  terminates.
- ▷ **Proof sketch:** All  $\mathcal{T}_1^f$  rules reduce the number of **connectives** and negative  $\forall$  or the multiplicity of positive  $\forall$ .
- ▷ **Theorem 15.1.47.**  $\mathcal{T}_1^f$  is only complete with **unbounded multiplicities**.
- ▷ **Proof sketch:** Replace  $p(a) \vee p(b)$  with  $p(a_1) \vee \dots \vee p(a_n)$  in Example 15.1.44.
- ▷ **Remark:** Otherwise validity in  $PL^1$  would be **decidable**.
- ▷ **Implementation:** We need an iterative **multiplicity deepening** process.

The other thing we need to realize is that there may be multiple ways we can use  $\mathcal{T}_1^f \perp$  to close a branch in a tableau, and – as  $\mathcal{T}_1^f \perp$  instantiates the whole tableau and not just the branch itself –

this choice matters.

### Treating $\mathcal{T}_1^f \perp$

- ▷ **Recall:** The  $\mathcal{T}_1^f \perp$  rule instantiates the whole tableau.
- ▷ **Problem:** There may be more than one  $\mathcal{T}_1^f \perp$  opportunity on a branch.
- ▷ **Example 15.1.48.** Choosing which matters – this tableau does not close!

$$\begin{array}{c}
 (\exists x. (p(a) \wedge p(b) \Rightarrow p()) \wedge (q(b) \Rightarrow q(x)))^F \\
 ((p(a) \wedge p(b) \Rightarrow p()) \wedge (q(b) \Rightarrow q(y)))^F \\
 (p(a) \Rightarrow p(b) \Rightarrow p())^F \quad (q(b) \Rightarrow q(y))^F \\
 \begin{array}{c} p(a)^T \\ p(b)^T \\ p(y)^F \\ \perp : [a/y] \end{array} \quad \left| \quad \begin{array}{c} q(b)^T \\ q(y)^F \end{array}
 \end{array}$$

choosing the other  $\mathcal{T}_1^f \perp$  in the left branch allows closure.

- ▷ **Idea:** Two ways of systematic proof search in  $\mathcal{T}_1^f$ :
  - ▷ backtracking search over  $\mathcal{T}_1^f \perp$  opportunities
  - ▷ saturate without  $\mathcal{T}_1^f \perp$  and find spanning matings (next slide)

The method of **spanning matings** follows the intuition that if we do not have good information on how to decide for a pair of **opposite literals** on a **branch** to use in  $\mathcal{T}_1^f \perp$ , we delay the choice by initially disregarding the rule altogether during saturation and then – in a later phase – looking for a configuration of cuts that have a joint overall **unifier**. The big advantage of this is that we only need to know that one exists, we do not need to compute or apply it, which would lead to exponential blow-up as we have seen above.

### Spanning Matings for $\mathcal{T}_1^f \perp$

- ▷ **Observation 15.1.49.**  $\mathcal{T}_1^f$  without  $\mathcal{T}_1^f \perp$  is terminating and confluent for given multiplicities.
- ▷ **Idea:** Saturate without  $\mathcal{T}_1^f \perp$  and treat all cuts at the same time (later).
- ▷ **Definition 15.1.50.**

Let  $\mathcal{T}$  be a  $\mathcal{T}_1^f$  tableau, then we call a unification problem  $\mathcal{E} := \mathbf{A}_1 = ? \mathbf{B}_1 \wedge \dots \wedge \mathbf{A}_n = ? \mathbf{B}_n$  a **mating** for  $\mathcal{T}$ , iff  $\mathbf{A}_i^T$  and  $\mathbf{B}_i^F$  occur in the same branch in  $\mathcal{T}$ .

We say that  $\mathcal{E}$  is a **spanning mating**, if  $\mathcal{E}$  is unifiable and every branch  $\mathcal{B}$  of  $\mathcal{T}$  contains  $\mathbf{A}_i^T$  and  $\mathbf{B}_i^F$  for some  $i$ .
- ▷ **Theorem 15.1.51.** A  $\mathcal{T}_1^f$ -tableau with a **spanning mating** induces a closed  $\mathcal{T}_1$  tableau.
- ▷ **Proof sketch:** Just apply the unifier of the **spanning mating**.

- ▷ **Idea:** Existence is sufficient, we do not need to compute the unifier.
- ▷ **Implementation:** Saturate without  $\mathcal{T}_1^f \perp$ , backtracking search for spanning matings with  $\mathcal{DU}$ , adding pairs incrementally.

**Excursion:** Now that we understand basic unification theory, we can come to the meta-theoretical properties of the tableau calculus. We delegate this discussion to??.

## 15.2 First-Order Resolution

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/26817>.

### First-Order Resolution (and CNF)

- ▷ **Definition 15.2.1.** The **first-order CNF calculus**  $CNF_1$  is given by the **inference rules** of  $CNF_0$  extended by the following **quantifier rules**:

$$\frac{(\forall X.A)^T \vee C \quad Z \notin (\text{free}(A) \cup \text{free}(C))}{([Z/X](A))^T \vee C}$$

$$\frac{(\forall X.A)^F \vee C \quad \{X_1, \dots, X_k\} = \text{free}(\forall X.A) \quad f \in \Sigma_k^{sk} \text{ new}}{([f(X_1, \dots, X_k)/X](A))^F \vee C}$$

the **first-order CNF**  $CNF_1(\Phi)$  of  $\Phi$  is the set of all **clauses** that can be derived from  $\Phi$ .

- ▷ **Definition 15.2.2 (First-Order Resolution Calculus).** The **First-order resolution calculus** ( $\mathcal{R}_1$ ) is a **test calculus** that manipulates formulae in **conjunctive normal form**.  $\mathcal{R}_1$  has two **inference rules**:

$$\frac{A^T \vee C \quad B^F \vee D \quad \sigma = \text{mgu}(A, B)}{(\sigma(C)) \vee (\sigma(D))} \qquad \frac{A^\alpha \vee B^\alpha \vee C \quad \sigma = \text{mgu}(A, B)}{(\sigma(A)) \vee (\sigma(C))}$$

### First-Order CNF – Derived Rules

- ▷ **Definition 15.2.3.** The following **inference rules** are **derivable** from the ones above via  $(\exists X.A) = \neg(\forall X.\neg A)$ :

$$\frac{(\exists X.A)^T \vee C \quad \{X_1, \dots, X_k\} = \text{free}(\forall X.A) \quad f \in \Sigma_k^{sk} \text{ new}}{([f(X_1, \dots, X_k)/X](A))^T \vee C}$$

$$\frac{(\exists X.A)^F \vee C \quad Z \notin (\text{free}(A) \cup \text{free}(C))}{([Z/X](A))^F \vee C}$$

**Excursion:** Again, we relegate the meta-theoretical properties of the first-order resolution calculus to??.

### 15.2.1 Resolution Examples

#### Col. West, a Criminal?

▷ **Example 15.2.4.** From [RN09]

The law says it is a crime for an American to sell weapons to hostile nations. The country Nono, an enemy of America, has some missiles, and all of its missiles were sold to it by Colonel West, who is American.

Prove that Col. West is a criminal.

- ▷ **Remark:** Modern resolution theorem provers prove this in less than 50ms.
- ▷ **Problem:** That is only true, if we **only** give the theorem prover exactly the right laws and background knowledge. If we give it all of them, it drowns in the combinatorial explosion.
- ▷ Let us build a resolution proof for the claim above.
- ▷ **But first** we must translate the situation into first-order logic clauses.
- ▷ **Convention:** In what follows, for better readability we will sometimes write implications  $P \wedge Q \wedge R \Rightarrow S$  instead of clauses  $P^F \vee Q^F \vee R^F \vee S^T$ .

#### Col. West, a Criminal?

- ▷ *It is a crime for an American to sell weapons to hostile nations:*  
**Clause:**  $\text{ami}(X_1) \wedge \text{weap}(Y_1) \wedge \text{sell}(X_1, Y_1, Z_1) \wedge \text{host}(Z_1) \Rightarrow \text{crook}(X_1)$
- ▷ *Nono has some missiles:*  $\exists X.\text{own}(\text{NN}, X) \wedge \text{mle}(X)$   
**Clauses:**  $\text{own}(\text{NN}, c)^T$  and  $\text{mle}(c)$  ( $c$  is Skolem constant)
- ▷ *All of Nono's missiles were sold to it by Colonel West.*  
**Clause:**  $\text{mle}(X_2) \wedge \text{own}(\text{NN}, X_2) \Rightarrow \text{sell}(\text{West}, X_2, \text{NN})$
- ▷ *Missiles are weapons:*  
**Clause:**  $\text{mle}(X_3) \Rightarrow \text{weap}(X_3)$
- ▷ *An enemy of America counts as "hostile":*  
**Clause:**  $\text{enemy}(X_4, \text{USA}) \Rightarrow \text{host}(X_4)$
- ▷ *West is an American:*  
**Clause:**  $\text{ami}(\text{West})$
- ▷ *The country Nono is an enemy of America:*  
 $\text{enemy}(\text{NN}, \text{USA})$

### Col. West, a Criminal! PL1 Resolution Proof

$$\begin{array}{l}
 \text{ami}(X_1)^F \vee \text{weapon}(Y_1)^F \vee \text{sell}(X_1, Y_1, Z_1)^F \vee \text{hostile}(Z_1)^F \vee \text{crook}(X_1)^T \text{ crook}(\text{West})^F \\
 \text{ami}(\text{West})^T \quad \text{ami}(\text{West})^F \vee \text{weapon}(Y_1)^F \vee \text{sell}(\text{West}, Y_1, Z_1)^F \vee \text{hostile}(Z_1)^F \\
 \text{missile}(X_3)^F \vee \text{weapon}(X_3)^T \quad \text{weapon}(Y_1)^F \vee \text{sell}(\text{West}, Y_1, Z_1)^F \vee \text{hostile}(Z_1)^F \\
 \text{missile}(c)^T \text{ missile}(Y_1)^F \vee \text{sell}(\text{West}, Y_1, Z_1)^F \vee \text{hostile}(Z_1)^F \\
 \text{sell}(\text{West}, c, Z_1)^F \vee \text{hostile}(Z_1)^F \quad \text{missile}(X_2)^F \vee \text{own}(\text{NoNo}, X_2)^F \vee \text{sell}(\text{West}, X_2, \text{NoNo})^T \\
 \text{missile}(c)^T \quad \text{missile}(c)^F \vee \text{own}(\text{NoNo}, c)^F \vee \text{hostile}(\text{NoNo})^F \\
 \text{own}(\text{NoNo}, c)^T \quad \text{own}(\text{NoNo}, c)^F \vee \text{hostile}(\text{NoNo})^F \\
 \text{enemy}(X_4, \text{USA})^F \vee \text{hostile}(X_4)^T \quad \text{hostile}(\text{NoNo})^F \\
 \text{enemy}(\text{NoNo}, \text{USA})^T \quad \text{enemy}(\text{NoNo}, \text{USA})^F \\
 \square
 \end{array}$$

Michael Kohlhase: Artificial Intelligence 1

457

### Curiosity Killed the Cat?

▷ **Example 15.2.5.** From [RN09]

Everyone who loves all animals is loved by someone.  
 Anyone who kills an animal is loved by noone.  
 Jack loves all animals.  
 Cats are animals.  
 Either Jack or curiosity killed the cat (whose name is "Garfield").

Prove that curiosity killed the cat.

Michael Kohlhase: Artificial Intelligence 1

458

2024-02-08

### Curiosity Killed the Cat? Clauses

▷ *Everyone who loves all animals is loved by someone:*  
 $\forall X. (\forall Y. \text{animal}(Y) \Rightarrow \text{love}(X, Y)) \Rightarrow (\exists \text{love}(Z, X))$   
**Clauses:**  $\text{animal}(g(X_1))^T \vee \text{love}(g(X_1), X_1)^T$  and  $\text{love}(X_2, f(X_2))^F \vee \text{love}(g(X_2), X_2)^T$

▷ *Anyone who kills an animal is loved by noone:*  
 $\forall X. \exists Y. \text{animal}(Y) \wedge \text{kill}(X, Y) \Rightarrow (\forall. \neg \text{love}(Z, X))$   
**Clause:**  $\text{animal}(Y_3)^F \vee \text{kill}(X_3, Y_3)^F \vee \text{love}(Z_3, X_3)^F$

▷ *Jack loves all animals:*

**Clause:**  $\text{animal}(X_4)^F \vee \text{love}(\text{jack}, X_4)^T$

▷ *Cats are animals:*  
**Clause:**  $\text{cat}(X_5)^F \vee \text{animal}(X_5)^T$

▷ *Either Jack or curiosity killed the cat (whose name is “Garfield”):*  
**Clauses:**  $\text{kill}(\text{jack}, \text{garf})^T \vee \text{kill}(\text{curiosity}, \text{garf})^T$  and  $\text{cat}(\text{garf})^T$

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 459 2024-02-08

### Curiosity Killed the Cat! PL1 Resolution Proof

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 460 2024-02-08

**Excursion:** A full analysis of any calculus needs a completeness proof. We will not cover this in the course, but provide one for the calculi introduced so far in??.

## 15.3 Logic Programming as Resolution Theorem Proving

**A Video Nugget** covering this section can be found at <https://fau.tv/clip/id/26820>. To understand **Prolog** better, we can interpret the language of **Prolog** as **resolution in PL<sup>1</sup>**.

### We know all this already

- ▷ Goals, goal sets, rules, and facts are just clauses. (called Horn clauses)
- ▷ **Observation 15.3.1 (Rule).**  $H: -B_1, \dots, B_n$ . corresponds to  $H^T \vee B_1^F \vee \dots \vee B_n^F$  (head the only positive literal)
- ▷ **Observation 15.3.2 (Goal set).**  $?- G_1, \dots, G_n$ . corresponds to  $G_1^F \vee \dots \vee G_n^F$
- ▷ **Observation 15.3.3 (Fact).**  $F$ . corresponds to the unit clause  $F^T$ .

▷ **Definition 15.3.4.** A **Horn clause** is a **clause** with at most one **positive literal**.

▷ **Recall:** **Backchaining** as search:

▷ state = tuple of **goals**; goal state = empty list (of **goals**).

▷  $next(\langle G, R_1, \dots, R_l \rangle) := \langle \sigma(B_1), \dots, \sigma(B_m), \sigma(R_1), \dots, \sigma(R_l) \rangle$  if there is a rule  $H: -B_1, \dots, B_m.$  and a **substitution**  $\sigma$  with  $\sigma(H) = \sigma(G)$ .

▷ **Note:** **Backchaining** becomes resolution

$$\frac{P^T \vee A \quad P^F \vee B}{A \vee B}$$

positive, unit-resulting hyperresolution (PURR)

This observation helps us understand **Prolog** better, and use **implementation** techniques from **automated theorem proving**.

## PROLOG (Horn Logic)

▷ **Definition 15.3.5.** A **clause** is called a **Horn clause**, iff contains at most one positive **literal**, i.e. if it is of the form  $B_1^F \vee \dots \vee B_n^F \vee A^T$  – i.e.  $A: -B_1, \dots, B_n.$  in **Prolog** notation.

▷ **Rule clause:** general case, e.g. `fallible(X) : human(X).`

▷ **Fact clause:** no negative **literals**, e.g. `human(sokrates).`

▷ **Program:** set of rule and fact **clauses**.

▷ **Query:** no positive **literals**: e.g. `?- fallible(X),greek(X).`

▷ **Definition 15.3.6.** **Horn logic** is the **formal system** whose language is the set of **Horn clauses** together with the **calculus**  $\mathcal{H}$  given by **MP**,  **$\wedge I$** , and **Subst**.

▷ **Definition 15.3.7.** A **logic program**  $P$  **entails** a **query**  $Q$  with **answer substitution**  $\sigma$ , iff there is a  $\mathcal{H}$  derivation  $D$  of  $Q$  from  $P$  and  $\sigma$  is the combined **substitution** of the **Subst** instances in  $D$ .

## PROLOG: Our Example

▷ **Program:**

```
human(leibniz).
human(sokrates).
greek(sokrates).
fallible(X):-human(X).
```

▷ **Example 15.3.8 (Query).** `?- fallible(X),greek(X).`

▷ **Answer substitution:** `[sokrates/X]`

To gain an intuition for this quite abstract definition let us consider a concrete **knowledge base** about cars. Instead of writing down everything we know about cars, we only write down that cars are motor vehicles with four wheels and that a particular object  $c$  has a motor and four wheels. We can see that the fact that  $c$  is a car can be derived from this. Given our definition of a **knowledge base** as the deductive closure of the **facts** and **rule** explicitly written down, the assertion that  $c$  is a car is in the induced **knowledge base**, which is what we are after.

### Knowledge Base (Example)

▷ **Example 15.3.9.**  $\text{car}(c)$ . is in the knowledge base generated by

$\text{has\_motor}(c)$ .

$\text{has\_wheels}(c,4)$ .

$\text{car}(X) :- \text{has\_motor}(X), \text{has\_wheels}(X,4)$ .

$$\frac{\frac{m(c) \quad w(c, 4)}{m(c) \wedge w(c, 4)} \wedge I \quad \frac{m(x) \wedge w(x, 4) \Rightarrow \text{car}()}{m(c) \wedge w(c, 4) \Rightarrow \text{car}()} \text{Subst}}{\text{car}(c)} \text{MP}$$

In this very simple example  $\text{car}(c)$  is about the only **fact** we can derive, but in general, **knowledge bases** can be **infinite** (we will see examples below).

### Why Only Horn Clauses?

▷ General **clauses** of the form  $A_1, \dots, A_n : B_1, \dots, B_n$ .

▷ e.g.  $\text{greek}(\text{socrates}), \text{greek}(\text{perikles})$

- ▷ **Question:** Are there fallible greeks?
- ▷ **Indefinite answer:** Yes, Perikles or Sokrates
- ▷ **Warning:** how about **Sokrates and Perikles**?

▷ e.g.  $\text{greek}(\text{socrates}), \text{roman}(\text{socrates}) :-$ .

- ▷ **Query:** Are there fallible greeks?
- ▷ **Answer:** Yes, Sokrates, if he is not a roman
- ▷ **Is this abduction**?????

### Three Principal Modes of Inference

▷ **Definition 15.3.10.** **Deduction**  $\hat{=}$  knowledge extension

▷ **Example 15.3.11.**  $\frac{\text{rains} \Rightarrow \text{wet\_street} \quad \text{rains}}{\text{wet\_street}} D$

▷ **Definition 15.3.12.** **Abduction**  $\hat{=}$  explanation

▷ **Example 15.3.13.**  $\frac{\text{rains} \Rightarrow \text{wet\_street} \quad \text{wet\_street}}{\text{rains}} A$

▷ **Definition 15.3.14.** **Induction**  $\hat{=}$  learning general rules from examples

▷ **Example 15.3.15.**  $\frac{\text{wet\_street} \quad \text{rains}}{\text{rains} \Rightarrow \text{wet\_street}} I$

## Chapter 16

# Knowledge Representation and the Semantic Web

The field of “Knowledge Representation” is usually taken to be an area in [Artificial Intelligence](#) that studies the representation of knowledge in [formal systems](#) and how to leverage [inference](#) techniques to generate new knowledge items from existing ones. Note that this definition coincides with what we know as [logical systems](#) in this course. This is the view taken by the subfield of “description logics”, but restricted to the case, where the [logical systems](#) have an [entailment relation](#) to ensure applicability. This chapter is organized as follows. We will first give a general introduction to the concepts of knowledge representation using semantic networks – an early and very intuitive approach to knowledge representation – as an object-to-think-with. In section 16.2 we introduce the principles and services of logic-based knowledge-representation using a non-standard interpretation of [propositional logic](#) as the basis, this gives us a formal account of the taxonomic part of semantic networks. In ?? we introduce the logic *ACC* that adds relations (called “roles”) and restricted quantification and thus gives us the full expressive power of semantic networks. Thus *ACC* can be seen as a prototype description logic. In section 16.4 we show how description logics are applied as the basis of the “semantic web”.

### 16.1 Introduction to Knowledge Representation

[A Video Nugget](#) covering the introduction to knowledge representation can be found at <https://fau.tv/clip/id/27279>.

Before we start into the development of description logics, we set the stage by looking into alternatives for knowledge representation.

#### 16.1.1 Knowledge & Representation

To approach the question of knowledge representation, we first have to ask ourselves, what knowledge might be. This is a difficult question that has kept philosophers occupied for millennia. We will not answer this question in this course, but only allude to and discuss some aspects that are relevant to our cause of knowledge representation.

#### What is knowledge? Why Representation?

- ▷ Lots/all of (academic) disciplines deal with knowledge!
- ▷ According to Probst/Raub/Romhardt [PRR97]

The diagram illustrates the progression of knowledge representation through four stages, each with a corresponding example:

- Character Set**: "0", "9", "5", ".", ","
- Syntax**: 0,95
- Context**: Exchange rate 1 \$ = 0,95 €
- Networking**: Markt mechanisms concerning exchange rates

The flow is: Character Set → Glyphs → Data → Information → Knowledge.

▷ **For the purposes of this course:** Knowledge is the information necessary to support intelligent reasoning!

|                |                                         |
|----------------|-----------------------------------------|
| representation | can be used to determine                |
| set of words   | whether a word is admissible            |
| list of words  | the rank of a word                      |
| a lexicon      | translation and/or grammatical function |
| structure      | function                                |

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 467 2024-02-08

According to an influential view of [PRR97], knowledge appears in layers. Starting with a character set that defines a set of **glyphs**, we can add syntax that turns mere **strings** into **data**. Adding context information gives **information**, and finally, by relating the information to other **information** allows to **draw conclusions**, turning **information** into **knowledge**.

Note that we already have aspects of representation and function in the diagram at the top of the slide. In this, the additional functionality added in the successive layers gives the representations more and more functions, until we reach the knowledge level, where the function is given by **inferencing**. In the second example, we can see that representations determine possible functions.

Let us now strengthen our intuition about **knowledge** by contrasting knowledge representations from “regular” **data structures** in computation.

## Knowledge Representation vs. Data Structures

▷ **Idea:** Representation as structure **and** function.

- ▷ the **representation** determines the content theory (what is the data?)
- ▷ the **function** determines the process model (what do we do with the data?)

▷ **Question:** Why do we use the term “knowledge representation” rather than

- ▷ **data structures?** (sets, lists, ... above)
- ▷ **information representation?** (it is information)

▷ **Answer:**

No good reason other than **AI** practice, with the intuition that

- ▷ **data** is simple and general (supports many algorithms)
- ▷ **knowledge** is complex (has distinguished process model)

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 468 2024-02-08

As knowledge is such a central notion in **artificial intelligence**, it is not surprising that there are multiple approaches to dealing with it. We will only deal with the first one and leave the others to self-study.

## Some Paradigms for Knowledge Representation in AI/NLP

- ▷ GOFAI (good old-fashioned AI)
  - ▷ symbolic knowledge representation, process model based on heuristic search
- ▷ Statistical, corpus-based approaches.
  - ▷ symbolic representation, process model based on machine learning
  - ▷ knowledge is divided into symbolic- and statistical (search) knowledge
- ▷ The connectionist approach
  - ▷ sub-symbolic representation, process model based on primitive processing elements (nodes) and weighted links
  - ▷ knowledge is only present in activation patterns, etc.

When assessing the relative strengths of the respective approaches, we should evaluate them with respect to a pre-determined set of criteria.

## KR Approaches/Evaluation Criteria

- ▷ **Definition 16.1.1.** The evaluation criteria for knowledge representation approaches are:
  - ▷ **Expressive adequacy:** What can be represented, what distinctions are supported.
  - ▷ **Reasoning efficiency:** Can the representation support processing that generates results in acceptable speed?
  - ▷ **Primitives:** What are the primitive elements of representation, are they intuitive, cognitively adequate?
  - ▷ **Meta representation:** Knowledge about knowledge
  - ▷ **Completeness:** The problems of reasoning with knowledge that is known to be incomplete.

### 16.1.2 Semantic Networks

A **Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/27280>.

To get a feeling for early knowledge representation approaches from which description logics developed, we take a look at “semantic networks” and contrast them to logical approaches.

**Semantic networks** are a very simple way of arranging knowledge about **objects** and **concepts** and their relationships in a **graph**.

## Semantic Networks [CQ69]

- ▷ **Definition 16.1.2.** A **semantic network** is a **directed graph** for representing knowledge:

- ▷ nodes represent **objects** and **concepts** (classes of objects)  
(e.g. **John** (object) and **bird** (concept))
- ▷ edges (called **links**) represent relations between these (isa, father\_of, belongs\_to)

▷ **Example 16.1.3.** A **semantic network** for birds and persons:

- ▷ **Problem:** How do we derive new information from such a network?
- ▷ **Idea:** Encode taxonomic information about **objects** and **concepts** in special links (“isa” and “inst”) and specify property inheritance along them in the process model.

Even though the **network** in Example 16.1.3 is very intuitive (we immediately understand the **concepts** depicted), it is unclear how we (and more importantly a machine that does not associate **meaning** with the labels of the **nodes** and **edges**) can draw **inferences** from the “knowledge” represented.

## Deriving Knowledge Implicit in Semantic Networks

- ▷ **Observation 16.1.4.** *There is more knowledge in a **semantic network** than is explicitly written down.*
- ▷ **Example 16.1.5.** In the network below, we “know” that *robins have wings* and in particular, *Jack has wings*.

- ▷ **Idea:** Links labeled with “isa” and “inst” are special: they propagate properties encoded by other links.
- ▷ **Definition 16.1.6.** We call links labeled by
  - ▷ “isa” an **inclusion** or **isa link** (inclusion of concepts)
  - ▷ “inst” **instance** or **inst link** (concept membership)

We now make the idea of “propagating properties” rigorous by defining the notion of **derived relations**, i.e. the relations that are left implicit in the network, but can be added without changing its **meaning**.

## Deriving Knowledge Semantic Networks

- ▷ **Definition 16.1.7 (Inference in Semantic Networks).** We call all link labels except “inst” and “isa” in a semantic network **relations**.

Let  $N$  be a semantic network and  $R$  a relation in  $N$  such that  $A \xrightarrow{\text{isa}} B \xrightarrow{R} C$  or  $A \xrightarrow{\text{inst}} B \xrightarrow{R} C$ , then we can **derive** a relation  $A \xrightarrow{R} C$  in  $N$ .

The process of **deriving** new **concepts** and **relations** from existing ones is called **inference** and **concepts/relations** that are only available via **inference implicit** (in a semantic network).

- ▷ **Intuition:** **Derived relations** represent knowledge that is implicit in the network; they could be added, but usually are not to avoid clutter.
- ▷ **Example 16.1.8.** **Derived relations** in Example 16.1.5

- ▷ **Slogan:** Get out more knowledge from a semantic networks than you put in.

Note that Definition 16.1.7 does not quite allow to **derive** that *Jack is a bird* (did you spot that “isa” is not a **relation** that can be inferred?), even though we know it is true in the world. This shows us that **inference** in semantic networks has to be very carefully defined and may not be “complete”, i.e. there are things that are true in the real world that our **inference** procedure does not capture.

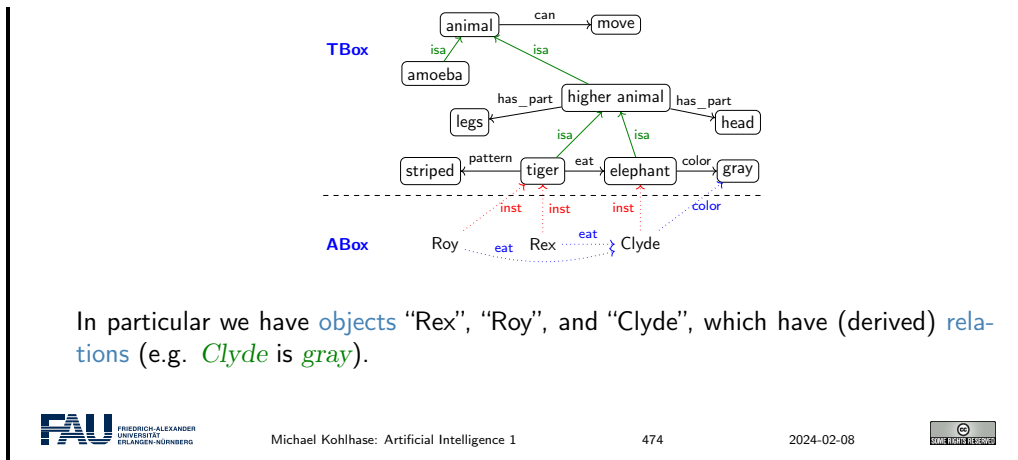

Dually, if we are not careful, then the **inference** procedure might **derive** properties that are not true in the real world even if all the properties explicitly put into the network are. We call such an **inference** procedure **unsound** or **incorrect**.

These are two general phenomena we have to keep an eye on.

Another problem is that **semantic networks** (e.g. in Example 16.1.3) confuse two kinds of **concepts**: individuals (represented by proper names like *John* and *Jack*) and **concepts** (nouns like *robin* and *bird*). Even though the **isa** and **inst** link already acknowledge this distinction, the “has\_part” and “loves” **relations** are at different levels entirely, but not distinguished in the networks.

## Terminologies and Assertions

- ▷ **Remark 16.1.9.** We should distinguish **concepts** from **objects**.
- ▷ **Definition 16.1.10.** We call the **subgraph** of a **semantic network**  $N$  spanned by the **isa** links and **relations** between **concepts** the **terminology** (or **TBox**, or the famous **Isa Hierarchy**) and the **subgraph** spanned by the **inst** links and **relations** between **objects**, the **assertions** (or **ABox**) of  $N$ .
- ▷ **Example 16.1.11.** In this **semantic network** we keep **objects concept** apart notationally:

But there are severe shortcomings of semantic networks: the suggestive shape and node names give (humans) a false sense of **meaning**, and the **inference rules** are only given in the process model (the **implementation** of the **semantic network** processing system).

This makes it very difficult to assess the strength of the **inference system** and make assertions e.g. about **completeness**.

### Limitations of Semantic Networks

- ▷ What is the **meaning** of a link?
  - ▷ link labels are very suggestive (misleading for humans)
  - ▷ **meaning** of link types defined in the process model (no denotational semantics)
- ▷ **Problem:** No distinction of optional and defining traits!
- ▷ **Example 16.1.12.** Consider a robin that has lost its wings in an accident:

“Cancel-links” have been proposed, but their status and process model are debatable.

To alleviate the perceived drawbacks of semantic networks, we can contemplate another notation that is more linear and thus more easily **implemented**: function/argument notation.

### Another Notation for Semantic Networks

- ▷ **Definition 16.1.13.** **Function/argument notation** for semantic networks
  - ▷ interprets **nodes** as arguments (reification to individuals)
  - ▷ interprets **links** as functions (predicates actually)
- ▷ **Example 16.1.14.**

```

 graph TD
 bird -- isa --> robin
 bird -- has_part --> wings
 Jack -- inst --> robin
 Mary -- inst --> Person
 John -- owner_of --> Jack
 John -- loves --> Mary

```

isa(robin,bird)  
 haspart(bird,wings)  
 inst(Jack,robin)  
 owner\_of(John, robin)  
 loves(John,Mary)

▷ **Evaluation:**

- + linear notation (equivalent, but better to implement on a computer)
- + easy to give process model by deduction (e.g. in Prolog)
- worse locality properties (networks are associative)

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 476 2024-02-08

Indeed the function/argument notation is the immediate idea how one would naturally represent semantic networks for **implementation**.

This notation has been also characterized as subject/predicate/object triples, alluding to simple (English) sentences. This will play a role in the “semantic web” later.

Building on the **function/argument notation** from above, we can now give a formal semantics for **semantic network**: we translate them into **first-order logic** and use the semantics of that.

### A Denotational Semantics for Semantic Networks

▷ **Observation:** If we handle *isa* and *inst* links specially in **function/argument notation**

```

 graph TD
 bird -- isa --> robin
 bird -- has_part --> wings
 Jack -- inst --> robin
 Mary -- inst --> Person
 John -- owner_of --> Jack
 John -- loves --> Mary

```

robin  $\subseteq$  bird  
 haspart(bird,wings)  
 Jack  $\in$  robin  
 owner\_of(John, Jack)  
 loves(John,Mary)

it looks like **first-order logic**, if we take

- ▷  $a \in S$  to mean  $S(a)$  for an **object**  $a$  and a **concept**  $S$ .
- ▷  $A \subseteq B$  to mean  $\forall X. A(X) \Rightarrow B(X)$  and **concepts**  $A$  and  $B$
- ▷  $R(A, B)$  to mean  $\forall X. A(X) \Rightarrow (\exists Y. B(Y) \wedge R(X, Y))$  for a **relation**  $R$ .

▷ **Idea:** Take first-order deduction as process model (gives inheritance for free)

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 477 2024-02-08

Indeed, the semantics induced by the translation to first-order logic, gives the intuitive **meaning** to the semantic networks. Note that this only holds only for the features of semantic networks that are representable in this way, e.g. the “cancel links” shown above are not (and that is a feature, not a **bug**).

But even more importantly, the translation to first-order logic gives a first process model: we can use first-order inference to compute the set of inferences that can be drawn from a semantic network.

Before we go on, let us have a look at an important application of knowledge representation technologies: the **semantic web**.

### 16.1.3 The Semantic Web

A **Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/27281>. We will now define the term **semantic web** and discuss the pertinent ideas involved. There are two central ones, we will cover here:

- Information and data come in different levels of explicitness; this is usually visualized by a “ladder” of information.
- if information is sufficiently machine-understandable, then we can automate drawing conclusions.

## The Semantic Web

▷ **Definition 16.1.15.** The **semantic web** is the result including of semantic content in **web pages** with the aim of converting the **WWW** into a machine-understandable “web of data”, where **inference** based services can add value to the ecosystem.

▷ **Idea:** Move web content up the ladder, use **inference** to make connections.

The diagram illustrates the Semantic Web ladder with four levels, each represented by a circle above a corresponding box:

- Character Set:** Circle contains "0", "9", "5", "1". Box below is **Glyphs**.
- Syntax:** Circle contains "0,95". Box below is **Data**.
- Context:** Circle contains "Exchange rate 1 \$ = 0,95 €". Box below is **Information**.
- Networking:** Circle contains "Markt mechanisms concerning exchange rates". Box below is **Knowledge**.

Arrows point from Glyphs to Data, Data to Information, and Information to Knowledge.

▷ **Example 16.1.16.** Information not explicitly represented (in one place)

**Query:** *Who was US president when Barak Obama was born?*  
**Google:** ... *BIRTH DATE: August 04, 1961...*

**Query:** *Who was US president in 1961?*  
**Google:** *President: Dwight D. Eisenhower [...] John F. Kennedy (starting Jan. 20.)*

Humans understand the text and combine the information to get the answer. Machines need more than just text  $\rightsquigarrow$  **semantic web** technology.

Michael Kohlhase: Artificial Intelligence 1
478
2024-02-08

The term “**semantic web**” was coined by Tim Berners Lee in analogy to **semantic networks**, only applied to the world wide web. And as for **semantic networks**, where we have **inference** processes that allow us to recover information that is not explicitly represented from the network (here the world-wide-web).

To see that problems have to be solved, to arrive at the **semantic web**, we will now look at a concrete example about the “semantics” in **web pages**. Here is one that looks typical enough.

### What is the Information a User sees?

- ▷ **Example 16.1.17.** Take the following web-site with a conference announcement

WWW2002  
 The eleventh International World Wide Web Conference  
 Sheraton Waikiki Hotel  
 Honolulu, Hawaii, USA

### Solution: XML markup with “meaningful” Tags

▷ **Example 16.1.19.** Let’s annotate (parts of) the meaning via XML markup

```

<title>WWW€€€
T(1)1[1]E|u(Zu)u\+u)\-+WvD[1W]11W|[C\{1V1\1}</title>
<place>S(1V-u\W+))||)HlW]Hl\HnDnH-H-3-))€USA</place>
<date>K_∞∞M+€€€</date>
<participants>R1})u1V1[√-VU))√-u1J1D)\}{V1D
A111V1+€)+€C-1+[+€C(1)1D1\H-HV||€FV-1\1]€G1V1+€)+€G(-1+€H\})K\})€Z1(1)+€
ZV1]1+€)+€Z1+€)+€JH-1\€M+€1+€M13Z1+€)+€T(1M1u(1V1+€)+€f€M1V3+€)+€
S\})+√1V1€S3)u1]1V1+€)+€u(1U\1u(1K)\})1D€u(1U\1u(1S1+u1]f€V)1u\+€)+€Z-1)V1
</participants>
<introduction>O\1u(1u(M+Hl\HnDn3))11√V1E)11u(1[+1]11V1√1{u(111E1|u(Zu)u\
\+u)\-+WvD[1W]11W|[C\{1V1\1}</introduction>
<program>S√1+111V1J1\})V11[
<speaker>T1D1V1\1V1K11-11D)1u(13)111\3\1E1\1u1V1{u(1W1</speaker>
<speaker>I+1J1u1V1-I-1\1u(1√111V1{u(1GV)1€u(11]§u}11V1+€)+€)\1u(1V1u<speaker>
</program>

```

But does this really help? Is conventional wisdom correct?

### What can we do with this?

▷ **Example 16.1.20.** Consider the following fragments:

```

R1u1]1TWWW€€€
T(1)1[1]E|u(Zu)u\+u)\-+WvD[1W]11W|[C\{1V1\1}R∞u)u1]1T
R√1+€)+€T S(1V-u\W+))||)HlW]Hl\HnDnH-H-3-))€USA R∞√1+€)+€T
R[-u1]TK_∞∞M+€€€R∞[-u1]T

```

Given the markup above, a machine agent can

- ▷ parse ∞∞M+€€€ as the date May 7 11 2002 and add this to the user’s calendar,
- ▷ parse S(1V-u\W+))||)HlW]Hl\HnDnH-H-3-))€USA as a destination and find flights.

▷ **But:** do not be deceived by your ability to understand English!

To understand what a machine can understand we have to obfuscate the markup as well, since it does not carry any intrinsic meaning to the machine either.

### What the machine sees of the XML

▷ **Example 16.1.21.** Here is what the machine sees of the XML

```

<title>WWW€€€
T(1)1[1]E|u(Zu)u\+u)\-+WvD[1W]11W|[C\{1V1\1}</u>1]1>

```

So we have not really gained much either with the **markup**, we really have to give **meaning** to the **markup** as well, this is where techniques from semantic web come into play. To understand how we can make the web more semantic, let us first take stock of the current status of (markup on) the web. It is well-known that world-wide-web is a hypertext, where **multimedia** documents (text, **images**, videos, etc. and their fragments) are connected by **hyperlinks**. As we have seen, all of these are largely opaque (non-understandable), so we end up with the following situation (from the viewpoint of a machine).

### The Current Web

- ▷ **Resources:** identified by URIs, untyped
- ▷ **Links:** href, src, ... limited, non-descriptive
- ▷ **User:** Exciting world - semantics of the resource, however, gleaned from content
- ▷ **Machine:** Very little information available - significance of the links only evident from the context around the anchor.

Let us now contrast this with the envisioned **semantic web**.

### The Semantic Web

- ▷ **Resources:** Globally identified by URIs or Locally scoped (Blank), Extensible, Relational.
- ▷ **Links:** Identified by URIs, Extensible, Relational.
- ▷ **User:** Even more exciting world, richer user experience.
- ▷ **Machine:** More processable information is available (Data Web).
- ▷ **Computers and people:** Work, learn and exchange knowledge effectively.

Essentially, to make the web more machine-processable, we need to classify the resources by the concepts they represent and give the links a **meaning** in a way, that we can do inference with that. The ideas presented here gave rise to a set of technologies jointly called the “semantic web”, which we will now summarize before we return to our logical investigations of knowledge representation techniques.

### Towards a “Machine-Actionable Web”

- ▷ **Recall:** We need external agreement on **meaning** of annotation tags.
  - ▷ **Idea:** standardize them in a community process (e.g. DIN or ISO)
  - ▷ **Problem:** Inflexible, Limited number of things can be expressed
  - ▷ **Better:** Use **ontologies** to specify **meaning** of annotations
    - ▷ Ontologies provide a vocabulary of terms
    - ▷ New terms can be formed by combining existing ones
    - ▷ **Meaning (semantics)** of such terms is formally specified
    - ▷ Can also specify relationships between terms in multiple ontologies
  - ▷ Inference with annotations and ontologies (get out more than you put in!)
    - ▷ Standardize annotations in **RDF** [KC04] or **RDFa** [Her+13b] and ontologies on **OWL** [OWL09]
    - ▷ Harvest **RDF** and **RDFa** in to a **triplestore** or **OWL** reasoner.
    - ▷ **Query** that for implied knowledge (e.g. **chaining multiple facts from Wikipedia**)
- SPARQL:** Who was US President when Barack Obama was Born?  
**DBpedia:** John F. Kennedy (was president in August 1961)

### 16.1.4 Other Knowledge Representation Approaches

A **Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/27282>.

Now that we know what semantic networks mean, let us look at a couple of other approaches that were influential for the development of knowledge representation. We will just mention them for reference here, but not cover them in any depth.

#### Frame Notation as Logic with Locality

- ▷ Predicate Logic: (where is the locality?)

$catch\_22 \in catch\_object$       There is an instance of catching  
 $catcher(catch\_22, jack\_2)$       Jack did the catching  
 $caught(catch\_22, ball\_5)$       He caught a certain ball

- ▷ **Definition 16.1.22. Frames** (group everything around the object)

```
(catch_object catch_22
 (catcher jack_2)
 (caught ball_5))
```

- + Once you have decided on a **frame**, all the information is local
- + easy to define schemes for concept (aka. types in feature structures)
- how to determine **frame**, when to choose **frame** (log/chair)

#### KR involving Time (Scripts [Shank '77])

- ▷ **Idea:** Organize typical event sequences, actors and props into representation.

- ▷ **Definition 16.1.23.** A **script** is a structured representation describing a stereotyped sequence of events in a particular context. Structurally, **scripts** are very much like **frames**, except the values that fill the slots must be ordered.

- ▷ **Example 16.1.24.** getting your hair cut (at a beauty parlor)

- ▷ props, actors as “script variables”
- ▷ events in a (generalized) sequence

- ▷ use **script** material for

- ▷ **anaphora**, bridging references
- ▷ default common ground
- ▷ to fill in missing material into situations

### Other Representation Formats (not covered)

- ▷ Procedural Representations (production systems)
- ▷ Analogical representations (interesting but not here)
- ▷ Iconic representations (interesting but very difficult to formalize)
- ▷ **If you are interested, come see me off-line**

Michael Kohlhase: Artificial Intelligence 1

## 16.2 Logic-Based Knowledge Representation

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/27297>.

We now turn to knowledge representation approaches that are based on some kind of **logical system**. These have the advantage that we know exactly what we are doing: as they are based on symbolic representations and declaratively given **inference calculi** as process models, we can inspect them thoroughly and even prove facts about them.

### Logic-Based Knowledge Representation

- ▷ Logic (and related formalisms) have a well-defined semantics
  - ▷ explicitly (gives more understanding than statistical/neural methods)
  - ▷ transparently (symbolic methods are monotonic)
  - ▷ systematically (we can prove theorems about our systems)
- ▷ Problems with logic-based approaches
  - ▷ Where does the world knowledge come from? (Ontology problem)
  - ▷ How to guide search induced by logical **calculi** (combinatorial explosion)
- ▷ **One possible answer:** **description logics**. (next couple of times)

Michael Kohlhase: Artificial Intelligence 1
490
2024-02-08

But of course logic-based approaches have big drawbacks as well. The first is that we have to obtain the symbolic representations of knowledge to do anything – a non-trivial challenge, since most knowledge does not exist in this form in the wild, to obtain it, some agent has to experience the word, pass it through its cognitive apparatus, conceptualize the phenomena involved, systematize them sufficiently to form symbols, and then represent those in the respective formalism at hand.

The second drawback is that the process models induced by logic-based approaches (inference with calculi) are quite intractable. We will see that all inferences can be played back to satisfiability tests in the underlying logical system, which are exponential at best, and **undecidable** or even incomplete at worst.

Therefore a major thrust in logic-based knowledge representation is to investigate logical systems that are expressive enough to be able to represent most knowledge, but still have a **decidable** – and maybe even tractable in practice – satisfiability problem. Such logics are called “**description logics**”. We will study the basics of such logical systems and their inference procedures in the following.

### 16.2.1 Propositional Logic as a Set Description Language

Before we look at “real” description logics in ??, we will make a “dry run” with a logic we already understand: propositional logic, which we will re-interpret the system as a set description language by giving a new, non-standard semantics. This allows us to already preview most of the inference procedures and knowledge services of knowledge representation systems in the next subsection.

To establish propositional logic as a set description language, we use a different interpretation than usual. We interpret propositional variables as names of sets and the connectives as set operations, which is why we give them a different – more suggestive – syntax.

#### Propositional Logic as Set Description Language

- ▷ **Idea:** Use propositional logic as a set description language: (variant syntax/semantics)
- ▷ **Definition 16.2.1.** Let  $PL_{DL}^0$  be given by the following grammar for the  $PL_{DL}^0$  concepts. (formulae)

$$\mathcal{L} ::= C \mid \top \mid \perp \mid \bar{\mathcal{L}} \mid \mathcal{L} \sqcap \mathcal{L} \mid \mathcal{L} \sqcup \mathcal{L} \mid \mathcal{L} \sqsubseteq \mathcal{L} \mid \mathcal{L} \equiv \mathcal{L}$$

i.e.  $PL_{DL}^0$  formed from

- ▷ atomic formulae ( $\hat{=}$  propositional variables)
- ▷ concept intersection ( $\sqcap$ ) ( $\hat{=}$  conjunction  $\wedge$ )
- ▷ concept complement ( $\bar{\cdot}$ ) ( $\hat{=}$  negation  $\neg$ )
- ▷ concept union ( $\sqcup$ ), subsumption ( $\sqsubseteq$ ), and equivalence ( $\equiv$ ) defined from these. ( $\hat{=}$   $\vee, \Rightarrow$ , and  $\Leftrightarrow$ )

- ▷ **Definition 16.2.2 (Formal Semantics).**

Let  $\mathcal{D}$  be a given set (called the domain) and  $\varphi: \mathcal{V}_0 \rightarrow \mathcal{P}(\mathcal{D})$ , then we define

- ▷  $\llbracket P \rrbracket := \varphi(P)$ , (remember  $\varphi(P) \subseteq \mathcal{D}$ ).
- ▷  $\llbracket \mathbf{A} \sqcap \mathbf{B} \rrbracket := \llbracket \mathbf{A} \rrbracket \cap \llbracket \mathbf{B} \rrbracket$  and  $\llbracket \bar{\mathbf{A}} \rrbracket := \mathcal{D} \setminus \llbracket \mathbf{A} \rrbracket \dots$

- ▷ **Note:**  $\langle PL_{DL}^0, \mathcal{S}, \llbracket \cdot \rrbracket \rangle$ , where  $\mathcal{S}$  is the class of possible domains forms a logical system.

Michael Kohlhase: Artificial Intelligence 1
491
2024-02-08

The main use of the set-theoretic semantics for  $PL^0$  is that we can use it to give meaning to concept axioms, which we use to describe the “world”.

#### Concept Axioms

- ▷ **Observation:** Set-theoretic semantics of ‘true’ and ‘false’ ( $\top := \varphi \sqcup \bar{\varphi}$   $\perp := \varphi \sqcap \bar{\varphi}$ )

$$\llbracket \top \rrbracket = \llbracket p \rrbracket \cup \llbracket \bar{p} \rrbracket = \llbracket p \rrbracket \cup \mathcal{D} \setminus \llbracket p \rrbracket = \mathcal{D} \qquad \text{Analogously: } \llbracket \perp \rrbracket = \emptyset$$

- ▷ **Idea:** Use logical axioms to describe the world (Axioms restrict the class of admissible domain structures)

- ▷ **Definition 16.2.3.** A **concept axiom** is a  $PL_{DL}^0$  formula  $A$  that is assumed to be true in the world.
- ▷ **Definition 16.2.4 (Set-Theoretic Semantics of Axioms).**  $A$  is **true** in domain  $\mathcal{D}$  iff  $\llbracket A \rrbracket = \mathcal{D}$ .
- ▷ **Example 16.2.5.** A world with three **concepts** and no **concept axioms**

**Concept axioms** are used to restrict the set of admissible domains to the intended ones. In our situation, we require them to be true – as usual – which here means that they denote the whole domain  $\mathcal{D}$ .

Let us fortify our intuition about **concept axioms** with a simple example about the sibling relation. We give four **concept axioms** and study their effect on the admissible models by looking at the respective Venn diagrams. In the end we see that in all admissible models, the denotations of the **concepts** son and daughter are **disjoint**, and child is the union of the two – just as intended.

### Effects of Axioms to Siblings

- ▷ **Example 16.2.6.** We can use **concept axioms** to describe the world from Example 16.2.5.

| Axioms                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Semantics |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| $\text{son} \sqsubseteq \text{child}$<br>iff $\llbracket \text{son} \rrbracket \cup \llbracket \text{child} \rrbracket = \mathcal{D}$<br>iff $\llbracket \text{son} \rrbracket \subseteq \llbracket \text{child} \rrbracket$<br>$\text{daughter} \sqsubseteq \text{child}$<br>iff $\llbracket \text{daughter} \rrbracket \cup \llbracket \text{child} \rrbracket = \mathcal{D}$<br>iff $\llbracket \text{daughter} \rrbracket \subseteq \llbracket \text{child} \rrbracket$ |           |
| $\text{son} \sqcap \text{daughter}$<br>$\text{child} \sqsubseteq \text{son} \sqcup \text{daughter}$                                                                                                                                                                                                                                                                                                                                                                         |           |

The set-theoretic semantics introduced above is compatible with the regular semantics of **propositional logic**, therefore we have the same propositional **identities**. Their validity can be established directly from the settings in Definition 16.2.2.

### Propositional Identities

| Name     | for $\sqcap$                                                                                 | for $\sqcup$                                                                                 |
|----------|----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| Idempot. | $\varphi \sqcap \varphi = \varphi$                                                           | $\varphi \sqcup \varphi = \varphi$                                                           |
| Identity | $\varphi \sqcap \top = \varphi$                                                              | $\varphi \sqcup \perp = \varphi$                                                             |
| Absorpt. | $\varphi \sqcup \top = \top$                                                                 | $\varphi \sqcap \perp = \perp$                                                               |
| Commut.  | $\varphi \sqcap \psi = \psi \sqcap \varphi$                                                  | $\varphi \sqcup \psi = \psi \sqcup \varphi$                                                  |
| Assoc.   | $\varphi \sqcap (\psi \sqcap \theta) = (\varphi \sqcap \psi) \sqcap \theta$                  | $\varphi \sqcup (\psi \sqcup \theta) = (\varphi \sqcup \psi) \sqcup \theta$                  |
| Distrib. | $\varphi \sqcap (\psi \sqcup \theta) = (\varphi \sqcap \psi) \sqcup (\varphi \sqcap \theta)$ | $\varphi \sqcup (\psi \sqcap \theta) = (\varphi \sqcup \psi) \sqcap (\varphi \sqcup \theta)$ |
| Absorpt. | $\varphi \sqcap (\varphi \sqcup \theta) = \varphi$                                           | $\varphi \sqcup (\varphi \sqcap \theta) = \varphi$                                           |
| Morgan   | $\overline{\varphi \sqcap \psi} = \overline{\varphi} \sqcup \overline{\psi}$                 | $\overline{\varphi \sqcup \psi} = \overline{\varphi} \sqcap \overline{\psi}$                 |
| dneg     | $\overline{\overline{\varphi}} = \varphi$                                                    |                                                                                              |

Michael Kohlhase: Artificial Intelligence 1
494
2024-02-08

There is another way we can approach the set description interpretation of propositional logic: by translation into a logic that can express knowledge about sets – **first-order logic**.

### Set-Theoretic Semantics and Predicate Logic

▷ **Definition 16.2.7.** Translation into  $PL^1$  (borrow semantics from that)

- ▷ recursively add argument variable  $x$
- ▷ change back  $\sqcap, \sqcup, \sqsubseteq, \equiv$  to  $\wedge, \vee, \Rightarrow, \Leftrightarrow$
- ▷ universal closure for  $x$  at formula level.

| Definition                                                                                                                        | Comment                         |
|-----------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| $\overline{p}^{fo(x)} := p(x)$                                                                                                    |                                 |
| $\overline{\overline{\mathbf{A}}}^{fo(x)} := \mathbf{A}^{fo(x)}$                                                                  |                                 |
| $\overline{\mathbf{A} \sqcap \mathbf{B}}^{fo(x)} := \overline{\mathbf{A}}^{fo(x)} \wedge \overline{\mathbf{B}}^{fo(x)}$           | $\wedge$ vs. $\sqcap$           |
| $\overline{\mathbf{A} \sqcup \mathbf{B}}^{fo(x)} := \overline{\mathbf{A}}^{fo(x)} \vee \overline{\mathbf{B}}^{fo(x)}$             | $\vee$ vs. $\sqcup$             |
| $\overline{\mathbf{A} \sqsubseteq \mathbf{B}}^{fo(x)} := \overline{\mathbf{A}}^{fo(x)} \Rightarrow \overline{\mathbf{B}}^{fo(x)}$ | $\Rightarrow$ vs. $\sqsubseteq$ |
| $\overline{\mathbf{A} = \mathbf{B}}^{fo(x)} := \overline{\mathbf{A}}^{fo(x)} \Leftrightarrow \overline{\mathbf{B}}^{fo(x)}$       | $\Leftrightarrow$ vs. $=$       |
| $\overline{\mathbf{A}}^{fo} := (\forall x. \overline{\mathbf{A}}^{fo(x)})$                                                        | for formulae                    |

Michael Kohlhase: Artificial Intelligence 1
495
2024-02-08

Normally, we embed  $PL^0$  into  $PL^1$  by mapping **propositional variables** to **atomic propositions** and the **connectives** to themselves. The purpose of this embedding is to “talk about truth/falsity of assertions”. For “talking about sets” we use a non-standard embedding: propositional variables in  $PL^0$  are mapped to first-order predicates, and the **connectives** to corresponding set operations. This uses the convention that a set  $S$  is represented by a unary predicate  $p_S$  (its characteristic predicate), and set membership  $a \in S$  as  $p_S(a)$ .

## Translation Examples

- ▷ **Example 16.2.8.** We translate the **concept axioms** from Example 16.2.6 to fortify our intuition:

$$\begin{aligned} \overline{\text{son} \sqsubseteq \text{child}}^{fo} &= \forall x. \text{son}(x) \Rightarrow \text{child}(x) \\ \overline{\text{daughter} \sqsubseteq \text{child}}^{fo} &= \forall x. \text{daughter}(x) \Rightarrow \text{child}(x) \\ \overline{\text{son} \sqcap \text{daughter}}^{fo} &= \forall x. \overline{\text{son}(x) \wedge \text{daughter}(x)} \\ \overline{\text{child} \sqsubseteq \text{son} \sqcup \text{daughter}}^{fo} &= \forall x. \text{child}(x) \Rightarrow (\text{son}(x) \vee \text{daughter}(x)) \end{aligned}$$

- ▷ What are the advantages of translation to  $\text{PL}^1$ ?
- ▷ **theoretically:** A better understanding of the semantics
  - ▷ **computationally:** Description Logic Framework, but **NOTHING** for  $\text{PL}^0$ 
    - ▷ we can follow this pattern for richer **description logics**.
    - ▷ many tests are **decidable** for  $\text{PL}^0$ , but not for  $\text{PL}^1$ . (**Description Logics?**)

## 16.2.2 Ontologies and Description Logics

**A Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/27298>. We have seen how sets of **concept axioms** can be used to describe the “world” by restricting the set of admissible models. We want to call such concept descriptions “ontologies” – formal descriptions of (classes of) objects and their relations.

### Ontologies aka. “World Descriptions”

- ▷ **Definition 16.2.9 (Classical).** An **ontology** is a representation of the types, properties, and interrelationships of the entities that really or fundamentally exist for a particular **domain of discourse**.
- ▷ **Remark:** Definition 16.2.9 is very general, and depends on what we mean by “representation”, “entities”, “types”, and “interrelationships”.  
This may be a feature, and not a **bug**, since we can use the same intuitions across a variety of representations.
- ▷ **Definition 16.2.10.** An **ontology** consists of a **formal system**  $\langle \mathcal{L}, \mathcal{K}, \models, \mathcal{C} \rangle$  with **concept axiom** (expressed in  $\mathcal{L}$ ) about
- ▷ **individuals:** concrete entities in a **domain of discourse**,
  - ▷ **concepts:** particular collections of **individuals** that share properties and aspects – the **instances** of the **concept**, and
  - ▷ **relations:** ways in which **individuals** can be related to one another.
- ▷ **Example 16.2.11.** **Semantic networks** are **ontologies**. (**relatively informal**)
- ▷ **Example 16.2.12.**  $\text{PL}_{\text{DL}}^0$  is an **ontology** format. (**formal, but relatively weak**)

▷ **Example 16.2.13.**  $PL^1$  is an **ontology** format as well. (formal, expressive)

---

Michael Kohlhase: Artificial Intelligence 1
497
2024-02-08

As we will see, the situation for  $PL_{DL}^0$  is typical for formal **ontologies** (even though it only offers **concepts**), so we state the general **description logic** paradigm for **ontologies**. The important idea is that having a **formal system** as an **ontology** format allows us to capture, study, and **implement** ontological inference.

### The Description Logic Paradigm

---

▷ **Idea:** Build a whole family of **logics** for describing **sets** and their **relations**. (tailor their expressivity and computational properties)

▷ **Definition 16.2.14.** A **description logic** is a **formal system** for talking about **collections** of **objects** and their **relations** that is at least as expressive as  $PL^0$  with set-theoretic semantics and offers **individuals** and **relations**.

A **description logic** has the following four components:

- ▷ a **formal language**  $\mathcal{L}$  with **logical constants**  $\sqcap, \sqcup, \sqsubseteq,$  and  $\equiv,$
- ▷ a set-theoretic semantics  $\langle \mathcal{D}, [[\cdot]] \rangle,$
- ▷ a translation into **first-order logic** that is compatible with  $\langle \mathcal{D}, [[\cdot]] \rangle,$  and
- ▷ a **calculus** for  $\mathcal{L}$  that induces a **decision procedure** for  $\mathcal{L}$ -satisfiability.

$PL^1$   
 $\uparrow \psi$   
**DL**  
 $\uparrow \varphi$   
 $PL^0$

$\psi := \left\{ \begin{array}{l} C \mapsto p \in \Sigma_1^p \\ \sqcap \mapsto \cap \\ \sqcup \mapsto \cup \end{array} \right\}$

undecidable  
 -----  
 decidable

$\varphi := \left\{ \begin{array}{l} X \in \mathcal{V}_0 \mapsto C \\ \wedge \mapsto \cap \\ \neg \mapsto \neg \end{array} \right\}$

▷ **Definition 16.2.15.** Given a **description logic**  $\mathcal{D}$ , a  **$\mathcal{D}$  ontology** consists of

- ▷ a **terminology** (or **TBox**): **concepts** and **roles** and a set of **concept axioms** that describe them, and
- ▷ **assertions** (or **ABox**): a set of **individuals** and statements about **concept membership** and role relationships for them.

---

Michael Kohlhase: Artificial Intelligence 1
498
2024-02-08

For convenience we add **concept definitions** as a mechanism for defining new **concepts** from old ones. The so-defined **concepts** inherit the properties from the **concepts** they are defined from.

### TBoxes in Description Logics

---

▷ Let  $\mathcal{D}$  be a **description logic** with **concepts**  $\mathcal{C}$ .

▷ **Definition 16.2.16.** A **concept definition** is a pair  $c=C$ , where  $c$  is a new **concept name** and  $C \in \mathcal{C}$  is a  $\mathcal{D}$ -formula.

▷ **Definition 16.2.17.** A **concept definition**  $c=C$  is called **recursive**, iff  $c$  occurs in  $C$ .

▷ **Example 16.2.18.** We can define  $\text{mother} = \text{woman} \sqcap \text{has\_child}$ .

- ▷ **Definition 16.2.19.** An **TBox** is a **finite set** of **concept definitions** and **concept axioms**. It is called **acyclic**, iff it does not contain **recursive definitions**.
- ▷ **Definition 16.2.20.** A formula **A** is called **normalized** wrt. an **TBox**  $\mathcal{T}$ , iff it does not contain **concepts** defined in  $\mathcal{T}$ . (convenient)
- ▷ **Definition 16.2.21 (Algorithm).** (for arbitrary DLs)  
Input: A formula **A** and a **TBox**  $\mathcal{T}$ .
  - ▷ **While** [**A** contains **concept**  $c$  and  $\mathcal{T}$  a **concept definition**  $c=C$ ]
    - ▷ substitute  $c$  by  $C$  in **A**.
- ▷ **Lemma 16.2.22.** *This algorithm terminates for acyclic TBoxes, but results can be exponentially large.*

As  $PL_{DL}^0$  does not offer any guidance on this, we will leave the discussion of **ABoxes** to subsection 16.3.3 when we have introduced our first proper **description logic**  $\mathcal{ALC}$ .

### 16.2.3 Description Logics and Inference

A **Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/27299>.

Now that we have established the description logic paradigm, we will have a look at the inference services that can be offered on this basis.

Before we go into details of particular **description logics**, we must ask ourselves what kind of **inference** support we would want for building systems that support knowledge workers in building, maintaining and using **ontologies**. An example of such a system is the Protégé system [Pro], which can serve for guiding our intuition.

#### Kinds of Inference in Description Logics

- ▷ **Definition 16.2.23.** **Ontology systems** employ three main reasoning services:
  - ▷ **Consistency test:** is a **concept definition** satisfiable?
  - ▷ **Subsumption test:** does a **concept** subsume another?
  - ▷ **Instance test:** is an individual an example of a **concept**?
- ▷ **Problem:** decidability, complexity, algorithm

We will now through these inference-based tests separately.

The consistency test checks for **concepts** that do not/cannot have instances. We want to avoid such **concepts** in our **ontologies**, since they clutter the namespace and do not contribute any meaningful contribution.

#### Consistency Test

- ▷ **Definition 16.2.24.** We call a **concept**  $C$  **consistent**, iff there is no **concept**  $A$ , with both  $C \sqsubseteq A$  and  $C \sqsubseteq \bar{A}$ .
- ▷ Or equivalently:

▷ **Definition 16.2.25.** A **concept**  $C$  is called **inconsistent**, iff  $\llbracket C \rrbracket = \emptyset$  for all  $\mathcal{D}$ .

▷ **Example 16.2.26 (T-Box).**

|               |   |                                            |                             |
|---------------|---|--------------------------------------------|-----------------------------|
| man           | = | person $\sqcap$ has_Y                      | person with y-chromosome    |
| woman         | = | person $\sqcap$ $\overline{\text{has\_Y}}$ | person without y-chromosome |
| hermaphrodite | = | man $\sqcap$ woman                         | man and woman               |

▷ This specification is **inconsistent**, i.e.  $\llbracket \text{hermaphrodite} \rrbracket = \emptyset$  for all  $\mathcal{D}$ .

▷ **Algorithm:** Propositional satisfiability test (NP complete)  
we know how to do this, e.g. tableau, resolution.

 FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 501 2024-02-08 

Even though **consistency** in our example seems trivial, large **ontologies** can make machine support necessary. This is even more true for **ontologies** that change over time. Say that an **ontology** initially has the **concept definitions**  $\text{woman} = \text{person} \sqcap \text{long\_hair}$  and  $\text{man} = \text{person} \sqcap \text{bearded}$ , and then is modernized to a more biologically correct state. In the initial version the **concept** **hermaphrodite** is consistent, but becomes **inconsistent** after the renovation; the authors of the renovation should be made aware of this by the system.

The **subsumption test** determines whether the sets denoted by two **concepts** are in a **subset** relation. The main justification for this is that humans tend to be aware of **concept subsumption**, and tend to think in **taxonomic hierarchies**. To cater to this, the **subsumption test** is useful.

### Subsumption Test

▷ **Example 16.2.27.** In this case trivial

| axiom                                              | entailed subsumption relation |
|----------------------------------------------------|-------------------------------|
| man = person $\sqcap$ has_Y                        | man $\sqsubseteq$ person      |
| woman = person $\sqcap$ $\overline{\text{has\_Y}}$ | woman $\sqsubseteq$ person    |

▷ **Definition 16.2.28.**  $A$  **subsumes**  $B$  (modulo a set  $\mathcal{A}$  of **concept axioms**), iff  $\llbracket B \rrbracket \subseteq \llbracket A \rrbracket$  for all **interpretations**  $\mathcal{D}$  that **satisfy**  $\mathcal{A}$ .

▷ **Reduction to consistency test:** (need to implement only one)  
 $\mathcal{A} \Rightarrow (A \Rightarrow B)$  is **valid** iff  $\mathcal{A} \wedge A \wedge \neg B$  is **consistent**.

▷ **Observation:** Or equivalently, iff  $\mathcal{A} \Rightarrow B \Rightarrow A$  is **valid** in  $PL^0$ .

▷ **In our example:** person subsumes woman and man

 FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 502 2024-02-08 

The good news is that we can reduce the **subsumption test** to the **consistency test**, so we can re-use our existing **implementation**.

The main user-visible service of the **subsumption test** is to compute the actual **taxonomy** induced by an **ontology**.

### Classification

▷ The **subsumption relation** among **all** concepts (subsumption graph)

- ▷ Visualization of the **subsumption graph** for inspection (plausibility)
- ▷ **Definition 16.2.29.** **Classification** is the computation of the **subsumption graph**.
- ▷ **Example 16.2.30.** (not always so trivial)

If we take stock of what we have developed so far, then we can see  $PL_{DL}^0$  as a rational reconstruction of semantic networks restricted to the “isa” relation. We relegate the “instance” relation to subsection 16.3.3.

This reconstruction can now be used as a basis on which we can extend the expressivity and inference procedures without running into problems.

## 16.3 A simple Description Logic: ALC

In this section, we instantiate the description-logic paradigm further with the prototypical logic  $\mathcal{ALC}$ , which we will introduce now.

### 16.3.1 Basic ALC: Concepts, Roles, and Quantification

A **Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/27300>.

In this subsection, we instantiate the description-logic paradigm with the prototypical logic  $\mathcal{ALC}$ , which we will develop now.

#### Motivation for $\mathcal{ALC}$ (Prototype Description Logic)

- ▷ Propositional logic ( $PL^0$ ) is not expressive enough!
- ▷ **Example 16.3.1.** “mothers are women that have a child”
- ▷ **Reason:** There are no **quantifiers** in  $PL^0$  (existential ( $\exists$ ) and universal ( $\forall$ ))
- ▷ **Idea:** Use first-order predicate logic ( $PL^1$ )

$$\forall x. mother(x) \Leftrightarrow (woman(x) \wedge (\exists y. has\_child(x, y)))$$

- ▷ **Problem:** Complex **algorithms**, **non-termination** ( $PL^1$  is too expressive)
- ▷ **Idea:** Try to travel the middle ground  
More expressive than  $PL^0$  (**quantifiers**) but weaker than  $PL^1$ . (still tractable)
- ▷ **Technique:** Allow only “restricted quantification”, where quantified variables only range over values that can be reached via a **binary relation** like *has\_child*.

$\mathcal{ALC}$  extends the **concept** operators of  $\text{PL}_{\text{DL}}^0$  with binary relations (called “roles” in  $\mathcal{ALC}$ ). This gives  $\mathcal{ALC}$  the expressive power we had for the basic **semantic networks** from ??.

### Syntax of $\mathcal{ALC}$

- ▷ **Definition 16.3.2 (Concepts).** (aka. “predicates” in  $\text{PL}^1$  or “propositional variables” in  $\text{PL}_{\text{DL}}^0$ )  
Concepts in DLs represent collections of objects.
- ▷ ... like **classes** in OOP.
- ▷ **Definition 16.3.3 (Special Concepts).** The **top concept**  $\top$  (for “true” or “all”) and the **bottom concept**  $\perp$  (for “false” or “none”).
- ▷ **Example 16.3.4.** person, woman, man, mother, professor, student, car, BMW, computer, computer program, heart attack risk, furniture, table, leg of a chair, ...
- ▷ **Definition 16.3.5.** **Roles** represent **binary relations** (like in  $\text{PL}^1$ )
- ▷ **Example 16.3.6.** has\_child, has\_son, has\_daughter, loves, hates, gives\_course, executes\_computer\_program, has\_leg\_of\_table, has\_wheel, has\_motor, ...
- ▷ **Definition 16.3.7 (Grammar).** The formulae of  $\mathcal{ALC}$  are given by the following grammar:  $F_{\mathcal{ALC}} ::= C \mid \top \mid \perp \mid \overline{F_{\mathcal{ALC}}} \mid F_{\mathcal{ALC}} \sqcap F_{\mathcal{ALC}} \mid F_{\mathcal{ALC}} \sqcup F_{\mathcal{ALC}} \mid \exists R.F_{\mathcal{ALC}} \mid \forall R.F_{\mathcal{ALC}}$

$\mathcal{ALC}$  restricts the quantification to range all individuals reachable as **role successor**. The distinction between universal and existential **quantifiers** clarifies an implicit **ambiguity** in **semantic networks**.

### Syntax of $\mathcal{ALC}$ : Examples

- ▷ **Example 16.3.8.**  $\text{person} \sqcap \exists \text{has\_child}.\text{student}$   
 $\hat{=}$  The set of persons that have a child which is a student  
 $\hat{=}$  parents of students
- ▷ **Example 16.3.9.**  $\text{person} \sqcap \exists \text{has\_child}.\exists \text{has\_child}.\text{student}$   
 $\hat{=}$  grandparents of students
- ▷ **Example 16.3.10.**  $\text{person} \sqcap \exists \text{has\_child}.\exists \text{has\_child}.\text{(student} \sqcup \text{teacher)}$   
 $\hat{=}$  grandparents of students or teachers
- ▷ **Example 16.3.11.**  $\text{person} \sqcap \forall \text{has\_child}.\text{student}$   
 $\hat{=}$  parents whose children are **all** students
- ▷ **Example 16.3.12.**  $\text{person} \sqcap \forall \text{haschild}.\exists \text{has\_child}.\text{student}$   
 $\hat{=}$  grandparents, whose children **all** have at least one child that is a student

## More $\mathcal{ALC}$ Examples

- ▷ **Example 16.3.13.**  $\text{car} \sqcap \exists \text{has\_part}.\exists \overline{\text{made\_in.EU}}$   
 $\hat{=}$  cars that have at least one part that has not been made in the EU
- ▷ **Example 16.3.14.**  $\text{student} \sqcap \forall \text{audits\_course}.\text{graduatelevelcourse}$   
 $\hat{=}$  students, that only audit graduate level courses
- ▷ **Example 16.3.15.**  $\text{house} \sqcap \forall \text{has\_parking.off\_street} \hat{=}$  houses with off-street parking
- ▷ **Note:**  $p \sqsubseteq q$  can still be used as an abbreviation for  $\overline{p} \sqcup q$ .
- ▷ **Example 16.3.16.**  $\text{student} \sqcap \forall \text{audits\_course}.\left(\exists \text{has\_tutorial}.\top \sqsubseteq \forall \text{has\_TA.woman}\right)$   
 $\hat{=}$  students that only audit courses that either have no tutorial or tutorials that are TAed by women

As before we allow [concept definitions](#) so that we can express new [concepts](#) from old ones, and obtain more concise descriptions.

## $\mathcal{ALC}$ Concept Definitions

- ▷ **Idea:** Define new [concepts](#) from known ones.
- ▷ **Definition 16.3.17.** A [concept definition](#) is a pair consisting of a new [concept](#) name (the [definiendum](#)) and an  $\mathcal{ALC}$  formula (the [definiens](#)). [Concepts](#) that are not [definienda](#) are called [primitive](#).
- ▷ We extend the  $\mathcal{ALC}$  [grammar](#) from Definition 16.3.7 by the [production](#)

$$CD_{\mathcal{ALC}} ::= C = F_{\mathcal{ALC}}$$

- ▷ **Example 16.3.18.**

| Definition                                                                                                                                  | rec? |
|---------------------------------------------------------------------------------------------------------------------------------------------|------|
| $\text{man} = \text{person} \sqcap \exists \text{has\_chrom}.\overline{\text{Y\_chrom}}$                                                    | -    |
| $\text{woman} = \text{person} \sqcap \forall \text{has\_chrom}.\overline{\text{Y\_chrom}}$                                                  | -    |
| $\text{mother} = \text{woman} \sqcap \exists \text{has\_child}.\text{person}$                                                               | -    |
| $\text{father} = \text{man} \sqcap \exists \text{has\_child}.\text{person}$                                                                 | -    |
| $\text{grandparent} = \text{person} \sqcap \exists \text{has\_child}.\left(\text{mother} \sqcup \text{father}\right)$                       | -    |
| $\text{german} = \text{person} \sqcap \exists \text{has\_parents}.\text{german}$                                                            | +    |
| $\text{number\_list} = \text{empty\_list} \sqcup \exists \text{is\_first}.\text{number} \sqcap \exists \text{is\_rest}.\text{number\_list}$ | +    |

As before, we can normalize a [TBox](#) by definition expansion if it is [acyclic](#). With the introduction of [roles](#) and [quantification](#), [concept definitions](#) in  $\mathcal{ALC}$  have a more “interesting” way to be [cyclic](#) as Observation 16.3.23 shows.

## TBox Normalization in $\mathcal{ALC}$

- ▷ **Definition 16.3.19.** We call an *ALC* formula  $\varphi$  **normalized** wrt. a set of **concept definitions**, iff all **concepts** occurring in  $\varphi$  are **primitive**.
- ▷ **Definition 16.3.20.** Given a set  $\mathcal{D}$  of **concept definitions**, **normalization** is the process of replacing in an *ALC* formula  $\varphi$  all **occurrences** of **definienda** in  $\mathcal{D}$  with their **definiencia**.
- ▷ **Example 16.3.21 (Normalizing grandparent).**

```

grandparent
→ person ⊓ ∃has_child.(mother ⊔ father)
→ person ⊓ ∃has_child.(woman ⊓ ∃has_child.person ⊓ man ⊓ ∃has_child.person)
→ person ⊓ ∃has_child.(person ⊓ ∃has_chrom.Y_chrom ⊓ ∃has_child.person ⊓ person ⊓ ∃has_chrom.Y_chrom ⊓ ∃has_child.person)

```
- ▷ **Observation 16.3.22.** *Normalization results can be exponential.* (contain redundancies)
- ▷ **Observation 16.3.23.** *Normalization need not terminate on cyclic TBoxes.*
- ▷ **Example 16.3.24.**

```

german → person ⊓ ∃has_parents.german
 → person ⊓ ∃has_parents.(person ⊓ ∃has_parents.german)
 → ...

```

Michael Kohlhase: Artificial Intelligence 1

2024-02-08

Now that we have motivated and fixed the syntax of *ALC*, we will give it a formal semantics. The semantics of *ALC* is an extension of the set-theoretic semantics for  $PL^0$ , thus the **interpretation**  $[[\cdot]]$  assigns **subsets** of the **domain** to **concepts** and binary **relations** over the **domain** to **roles**.

### Semantics of *ALC*

- ▷ *ALC* semantics is an extension of the set-semantics of **propositional logic**.
- ▷ **Definition 16.3.25.** A **model** for *ALC* is a pair  $\langle \mathcal{D}, [[\cdot]] \rangle$ , where  $\mathcal{D}$  is a non-empty set called the **domain** and  $[[\cdot]]$  a mapping called the **interpretation**, such that

| Op. | formula semantics                                                                                                                     |
|-----|---------------------------------------------------------------------------------------------------------------------------------------|
|     | $[[c]] \subseteq \mathcal{D} = [\top] \quad [[\perp]] = \emptyset \quad [[r]] \subseteq \mathcal{D} \times \mathcal{D}$               |
| ¬   | $[[\bar{\varphi}]] = [\varphi] = \mathcal{D} \setminus [\varphi]$                                                                     |
| ⊓   | $[[\varphi \sqcap \psi]] = [\varphi] \cap [\psi]$                                                                                     |
| ⊔   | $[[\varphi \sqcup \psi]] = [\varphi] \cup [\psi]$                                                                                     |
| ∃R. | $[[\exists R.\varphi]] = \{x \in \mathcal{D} \mid \exists y. \langle x, y \rangle \in [R] \text{ and } y \in [\varphi]\}$             |
| ∀R. | $[[\forall R.\varphi]] = \{x \in \mathcal{D} \mid \forall y. \text{if } \langle x, y \rangle \in [R] \text{ then } y \in [\varphi]\}$ |

- ▷ Alternatively we can define the semantics of *ALC* by translation into  $PL^1$ .
- ▷ **Definition 16.3.26.** The translation of *ALC* into  $PL^1$  extends the one from Definition 16.2.7 by the following **quantifier** rules:

$$\overline{\forall R.\varphi}^{fo(x)} := (\forall y.R(x, y) \Rightarrow \bar{\varphi}^{fo(y)}) \quad \overline{\exists R.\varphi}^{fo(x)} := (\exists y.R(x, y) \wedge \bar{\varphi}^{fo(y)})$$

▷ **Observation 16.3.27.** *The set-theoretic semantics from Definition 16.3.25 and the “semantics-by-translation” from Definition 16.3.26 induce the same notion of satisfiability.*

We can now use the  $\mathcal{ALC}$  identities above to establish a useful normal form for  $\mathcal{ALC}$ . This will play a role in the inference procedures we study next.

The following identities will be useful later on. They can be proven directly with the settings from Definition 16.3.25; we carry this out for one of them below.

### $\mathcal{ALC}$ Identities

|   |                                                                             |   |                                                                             |
|---|-----------------------------------------------------------------------------|---|-----------------------------------------------------------------------------|
| 1 | $\exists R.\bar{\varphi} = \forall R.\bar{\varphi}$                         | 3 | $\forall R.\bar{\varphi} = \exists R.\bar{\varphi}$                         |
| 2 | $\forall R.(\varphi \sqcap \psi) = \forall R.\varphi \sqcap \forall R.\psi$ | 4 | $\exists R.(\varphi \sqcup \psi) = \exists R.\varphi \sqcup \exists R.\psi$ |

▷ Proof of 1

$$\begin{aligned}
 \llbracket \exists R.\bar{\varphi} \rrbracket &= \mathcal{D} \setminus \llbracket \exists R.\varphi \rrbracket &= \mathcal{D} \setminus \{x \in \mathcal{D} \mid \exists y. (\langle x, y \rangle \in [R] \text{ and } (y \in \llbracket \varphi \rrbracket))\} \\
 &= \{x \in \mathcal{D} \mid \text{not } \exists y. (\langle x, y \rangle \in [R] \text{ and } (y \in \llbracket \varphi \rrbracket))\} \\
 &= \{x \in \mathcal{D} \mid \forall y. \text{if } (\langle x, y \rangle \in [R]) \text{ then } (y \notin \llbracket \varphi \rrbracket)\} \\
 &= \{x \in \mathcal{D} \mid \forall y. \text{if } (\langle x, y \rangle \in [R]) \text{ then } (y \in (\mathcal{D} \setminus \llbracket \varphi \rrbracket))\} \\
 &= \{x \in \mathcal{D} \mid \forall y. \text{if } (\langle x, y \rangle \in [R]) \text{ then } (y \in \llbracket \bar{\varphi} \rrbracket)\} \\
 &= \llbracket \forall R.\bar{\varphi} \rrbracket
 \end{aligned}$$

The form of the identities (interchanging quantification with connectives) is reminiscent of identities in  $\text{PL}^1$ ; this is no coincidence as the “semantics by translation” of Definition 16.3.26 shows.

### Negation Normal Form

▷ **Definition 16.3.28 (NNF).** An  $\mathcal{ALC}$  formula is in **negation normal form (NNF)**, iff complement ( $\bar{\cdot}$ ) is only applied to **primitive concept**.

▷ Use the  $\mathcal{ALC}$  identities as rules to compute it. (in linear time)

▷ **Example 16.3.29.**

| example                                              | by rule                                                       |
|------------------------------------------------------|---------------------------------------------------------------|
| $\exists R.(\forall S.e \sqcap \forall S.d)$         |                                                               |
| $\mapsto \forall R.\forall S.e \sqcap \forall S.d$   | $\exists R.\bar{\varphi} \mapsto \forall R.\bar{\varphi}$     |
| $\mapsto \forall R.(\forall S.e \sqcup \forall S.d)$ | $\varphi \sqcap \psi \mapsto \bar{\varphi} \sqcup \bar{\psi}$ |
| $\mapsto \forall R.(\exists S.e \sqcup \forall S.d)$ | $\forall R.\bar{\varphi} \mapsto \exists R.\bar{\varphi}$     |
| $\mapsto \forall R.(\exists S.e \sqcup \forall S.d)$ | $\bar{\bar{\varphi}} \mapsto \varphi$                         |

Finally, we extend  $\mathcal{ALC}$  with an  $\text{ABox}$  component. This mainly means that we define two new assertions in  $\mathcal{ALC}$  and specify their semantics and  $\text{PL}^1$  translation.

### ALC with Assertions about Individuals

- ▷ **Definition 16.3.30.** We define the **assertions** for *ALC*
  - ▷ **Role assertions**  $a:\varphi$  (*a* is a  $\varphi$ )
  - ▷  $a R b$  (*a* stands in relation *R* to *b*)

assertions make up the **ABox** in *ALC*.

- ▷ **Definition 16.3.31.** Let  $\langle \mathcal{D}, [[\cdot]] \rangle$  be a **model** for *ALC*, then we define
  - ▷  $\llbracket a:\varphi \rrbracket = \top$ , iff  $\llbracket a \rrbracket \in \llbracket \varphi \rrbracket$ , and
  - ▷  $\llbracket a R b \rrbracket = \top$ , iff  $(\llbracket a \rrbracket, \llbracket b \rrbracket) \in \llbracket R \rrbracket$ .
- ▷ **Definition 16.3.32.** We extend the **PL<sup>I</sup>** translation of *ALC* to *ALC* assertions:
  - ▷  $\overline{a:\varphi}^{fo} := \overline{\varphi}^{fo(a)}$ , and
  - ▷  $\overline{a R b}^{fo} := R(a, b)$ .

Michael Kohlhase: Artificial Intelligence 1
513
2024-02-08

If we take stock of what we have developed so far, then we see that *ALC* as a rational reconstruction of semantic networks restricted to the “isa” and “instance” relations – which are the only ones that can really be given a denotational and operational semantics.

### 16.3.2 Inference for ALC

**Video Nuggets** covering this subsection can be found at <https://fau.tv/clip/id/27301> and <https://fau.tv/clip/id/27302>.

In this subsection we make good on the motivation from ?? that description logics enjoy tractable inference procedures: We present a tableau calculus for *ALC*, show that it is a **decision procedure**, and study its **complexity**.

### T<sub>ALC</sub>: A Tableau-Calculus for ALC

- ▷ **Recap Tableaux:** A tableau calculus develops an initial tableau in a tree-formed scheme using tableau extension rules.  
A **saturated** tableau (no rules applicable) constitutes a **refutation**, if all branches are **closed** (end in  $\perp$ ).
- ▷ **Definition 16.3.33.** The *ALC* **tableau calculus**  $T_{ALC}$  acts on assertions
  - ▷  $x:\varphi$  (*x* inhabits concept  $\varphi$ )
  - ▷  $x R y$  (*x* and *y* are in relation *R*)

where  $\varphi$  is a **normalized ALC concept in negation normal form** with the following rules:

$$\frac{x:c \quad x:\bar{c}}{\perp} T_{\perp}$$

$$\frac{x:\varphi \sqcap \psi}{\begin{array}{l} x:\varphi \\ x:\psi \end{array}} T_{\sqcap}$$

$$\frac{x:\varphi \sqcup \psi}{x:\varphi \mid x:\psi} T_{\sqcup}$$

$$\frac{x:\forall R.\varphi \quad x R y}{y:\varphi} T_{\forall}$$

$$\frac{x:\exists R.\varphi}{\begin{array}{l} x R y \\ y:\varphi \end{array}} T_{\exists}$$

- ▷ To test consistency of a concept  $\varphi$ , normalize  $\varphi$  to  $\psi$ , initialize the tableau with  $x:\psi$ , saturate. Open branches  $\leadsto$  consistent. ( $x$  arbitrary)

In contrast to the tableau calculi for theorem proving we have studied earlier,  $\mathcal{T}_{AC}$  is run in “model generation mode”. Instead of initializing the tableau with the axioms and the negated conjecture and hope that all branches will close, we initialize the  $\mathcal{T}_{AC}$  tableau with axioms and the “membership-conjecture” that a given concept  $\varphi$  is satisfiable – i.e.  $\varphi$  has a member  $x$ , and hope for branches that are open, i.e. that make the conjecture true (and at the same time give a model).

Let us now work through two very simple examples; one unsatisfiable, and a satisfiable one.

### $\mathcal{T}_{AC}$ Examples

- ▷ **Example 16.3.34 (Tableau Proofs).** We have two similar conjectures about children.

- ▷  $x:\forall\text{has\_child.man} \sqcap \exists\text{has\_child.man}$  (all sons, but a daughter)

|                                                                      |                         |
|----------------------------------------------------------------------|-------------------------|
| $x:\forall\text{has\_child.man} \sqcap \exists\text{has\_child.man}$ | initial                 |
| $x:\forall\text{has\_child.man}$                                     | $\mathcal{T}_{\sqcap}$  |
| $x:\exists\text{has\_child.man}$                                     | $\mathcal{T}_{\sqcap}$  |
| $x \text{ has\_child } y$                                            | $\mathcal{T}_{\exists}$ |
| $y:\overline{\text{man}}$                                            | $\mathcal{T}_{\exists}$ |
| $\perp$                                                              | $\mathcal{T}_{\perp}$   |
| inconsistent                                                         |                         |

- ▷  $x:\forall\text{has\_child.man} \sqcap \exists\text{has\_child.man}$  (only sons, and at least one)

|                                                                      |                         |
|----------------------------------------------------------------------|-------------------------|
| $x:\forall\text{has\_child.man} \sqcap \exists\text{has\_child.man}$ | initial                 |
| $x:\forall\text{has\_child.man}$                                     | $\mathcal{T}_{\sqcap}$  |
| $x:\exists\text{has\_child.man}$                                     | $\mathcal{T}_{\sqcap}$  |
| $x \text{ has\_child } y$                                            | $\mathcal{T}_{\exists}$ |
| $y:\text{man}$                                                       | $\mathcal{T}_{\exists}$ |
| open                                                                 |                         |

This tableau shows a model: there are two persons,  $x$  and  $y$ .  $y$  is the only child of  $x$ ,  $y$  is a man.

Another example: this one is more complex, but the concept is satisfiable.

### Another $\mathcal{T}_{AC}$ Example

- ▷ **Example 16.3.35.**  $\forall\text{has\_child.}(\text{ugrad} \sqcup \text{grad}) \sqcap \exists\text{has\_child.ugrad}$  is satisfiable.
- ▷ Let's try it on the board
  - ▷ Tableau proof for the notes

|   |                                                                                                                             |                         |
|---|-----------------------------------------------------------------------------------------------------------------------------|-------------------------|
| 1 | $x:\forall\text{has\_child}.\text{u}(\text{grad} \sqcup \text{grad}) \sqcap \exists\text{has\_child}.\text{u}(\text{grad})$ | initial                 |
| 2 | $x:\forall\text{has\_child}.\text{u}(\text{grad} \sqcup \text{grad})$                                                       | $\mathcal{T}_{\sqcap}$  |
| 3 | $x:\exists\text{has\_child}.\text{u}(\text{grad})$                                                                          | $\mathcal{T}_{\sqcap}$  |
| 4 | $x \text{ has\_child } y$                                                                                                   | $\mathcal{T}_{\exists}$ |
| 5 | $y:\text{u}(\text{grad})$                                                                                                   | $\mathcal{T}_{\exists}$ |
| 6 | $y:\text{u}(\text{grad} \sqcup \text{grad})$                                                                                | $\mathcal{T}_{\forall}$ |
| 7 | $y:\text{u}(\text{grad}) \quad y:\text{grad}$                                                                               | $\mathcal{T}_{\sqcup}$  |
| 8 | $\perp \quad \text{open}$                                                                                                   |                         |

The left branch is closed, the right one represents a model:  $y$  is a child of  $x$ ,  $y$  is a graduate student,  $x$  has exactly one child:  $y$ .

Michael Kohlhase: Artificial Intelligence 1
516
2024-02-08

After we got an intuition about  $\mathcal{T}_{\text{ALC}}$ , we can now study the properties of the calculus to determine that it is a decision procedure for  $\text{ALC}$ .

### Properties of Tableau Calculi

- ▷ We study the following properties of a tableau calculus  $\mathcal{C}$ :
  - ▷ **Termination**: there are no infinite sequences of inference rule applications.
  - ▷ **Soundness**: If  $\varphi$  is satisfiable, then  $\mathcal{C}$  terminates with an open branch.
  - ▷ **Completeness**: If  $\varphi$  is unsatisfiable, then  $\mathcal{C}$  terminates and all branches are closed.
  - ▷ **complexity** of the algorithm (time and space complexity).
- ▷ Additionally, we are interested in the complexity of satisfiability itself (as a benchmark)

Michael Kohlhase: Artificial Intelligence 1
517
2024-02-08

The soundness result for  $\mathcal{T}_{\text{ALC}}$  is as usual: we start with a model of  $x:\varphi$  and show that an  $\mathcal{T}_{\text{ALC}}$  tableau must have an open branch.

### Correctness

- ▷ **Lemma 16.3.36**. If  $\varphi$  satisfiable, then  $\mathcal{T}_{\text{ALC}}$  terminates on  $x:\varphi$  with open branch.
- ▷ *Proof*: Let  $\mathcal{M} := \langle \mathcal{D}, [\cdot] \rangle$  be a model for  $\varphi$  and  $w \in [\varphi]$ .
 

$$\mathcal{M} \models (x:\psi) \quad \text{iff} \quad [x] \in [\psi]$$

  1. We define  $[x] := w$  and  $\mathcal{M} \models x R y \quad \text{iff} \quad \langle x, y \rangle \in [R]$   
 $\mathcal{M} \models S \quad \text{iff} \quad \mathcal{I} \models c$  for all  $c \in S$
  2. This gives us  $\mathcal{M} \models (x:\varphi)$  (base case)
  3. If the branch is satisfiable, then either
    - ▷ no rule applicable to leaf, (open branch)
    - ▷ or rule applicable and one new branch satisfiable. (inductive case: next)
  4. There must be an open branch. (by termination)

Michael Kohlhase: Artificial Intelligence 1
518
2024-02-08

We complete the proof by looking at all the  $\mathcal{T}_{\text{ALC}}$  inference rules in turn.

## Case analysis on the rules

$\mathcal{T}_\sqcap$  applies then  $\mathcal{M} \models (x:\varphi \sqcap \psi)$ , i.e.  $\llbracket x \rrbracket \in \llbracket \varphi \sqcap \psi \rrbracket$   
so  $\llbracket x \rrbracket \in \llbracket \varphi \rrbracket$  and  $\llbracket x \rrbracket \in \llbracket \psi \rrbracket$ , thus  $\mathcal{M} \models (x:\varphi)$  and  $\mathcal{M} \models (x:\psi)$ .

$\mathcal{T}_\sqcup$  applies then  $\mathcal{M} \models (x:\varphi \sqcup \psi)$ , i.e.  $\llbracket x \rrbracket \in \llbracket \varphi \sqcup \psi \rrbracket$   
so  $\llbracket x \rrbracket \in \llbracket \varphi \rrbracket$  or  $\llbracket x \rrbracket \in \llbracket \psi \rrbracket$ , thus  $\mathcal{M} \models (x:\varphi)$  or  $\mathcal{M} \models (x:\psi)$ ,  
wlog.  $\mathcal{M} \models (x:\varphi)$ .

$\mathcal{T}_\forall$  applies then  $\mathcal{M} \models (x:\forall R.\varphi)$  and  $\mathcal{M} \models x R y$ , i.e.  $\llbracket x \rrbracket \in \llbracket \forall R.\varphi \rrbracket$  and  $\langle x, y \rangle \in \llbracket R \rrbracket$ , so  
 $\llbracket y \rrbracket \in \llbracket \varphi \rrbracket$

$\mathcal{T}_\exists$  applies then  $\mathcal{M} \models (x:\exists R.\varphi)$ , i.e.  $\llbracket x \rrbracket \in \llbracket \exists R.\varphi \rrbracket$ ,  
so there is a  $v \in D$  with  $\langle \llbracket x \rrbracket, v \rangle \in \llbracket R \rrbracket$  and  $v \in \llbracket \varphi \rrbracket$ .  
We define  $\llbracket y \rrbracket := v$ , then  $\mathcal{M} \models x R y$  and  $\mathcal{M} \models (y:\varphi)$

For the **completeness** result for  $\mathcal{T}_{\mathcal{ALC}}$  we have to start with an **open tableau branch** and construct a **model** that **satisfies** all **judgments** in the **branch**. We proceed by building a **Herbrand model**, whose **domain** consists of all the **individuals** mentioned in the **branch** and which **interprets** all **concepts** and **roles** as specified in the **branch**. Not surprisingly, the **model** thus constructed **satisfies** (all **judgments** on) the **branch**.

## Completeness of the Tableau Calculus

▷ **Lemma 16.3.37.** *Open saturated tableau branches for  $\varphi$  induce models for  $\varphi$ .*

▷ *Proof:* construct a **model** for the **branch** and verify for  $\varphi$

1. Let  $\mathcal{B}$  be an **open, saturated branch**

▷ we define

$$\mathcal{D} := \{x \mid x:\psi \in \mathcal{B} \text{ or } z R x \in \mathcal{B}\}$$

$$\llbracket c \rrbracket := \{x \mid x:c \in \mathcal{B}\}$$

$$\llbracket R \rrbracket := \{\langle x, y \rangle \mid x R y \in \mathcal{B}\}$$

▷ well-defined since never  $x:c, x:\bar{c} \in \mathcal{B}$  (otherwise  $\mathcal{T}_\perp$  applies)

▷  $\mathcal{M}$  satisfies all **assertions**  $x:c, x:\bar{c}$  and  $x R y$ , (by construction)

2.  $\mathcal{M} \models (y:\psi)$ , for all  $y:\psi \in \mathcal{B}$  (on  $k = \text{size}(\psi)$  next slide)

3.  $\mathcal{M} \models (x:\varphi)$ .

We complete the proof by looking at all the  $\mathcal{T}_{\mathcal{ALC}}$  inference rules in turn.

## Case Analysis for Induction

**case**  $y:\psi = y:\psi_1 \sqcap \psi_2$  Then  $\{y:\psi_1, y:\psi_2\} \subseteq \mathcal{B}$  ( $\mathcal{T}_\sqcap$ -rule, saturation)

so  $\mathcal{M} \models (y:\psi_1)$  and  $\mathcal{M} \models (y:\psi_2)$  and  $\mathcal{M} \models (y:\psi_1 \sqcap \psi_2)$  (IH, Definition)

**case**  $y:\psi = y:\psi_1 \sqcup \psi_2$  Then  $y:\psi_1 \in \mathcal{B}$  or  $y:\psi_2 \in \mathcal{B}$  ( $\mathcal{T}_\sqcup$ , saturation)

so  $\mathcal{M} \models (y:\psi_1)$  or  $\mathcal{M} \models (y:\psi_2)$  and  $\mathcal{M} \models (y:\psi_1 \sqcup \psi_2)$  (IH, Definition)

case  $y:\psi = y:\exists R.\theta$  then  $\{y R z, z:\theta\} \subseteq B$  ( $z$  new variable) ( $\mathcal{T}_{\exists}$ -rules, saturation)

so  $\mathcal{M} \models (z:\theta)$  and  $\mathcal{M} \models y R z$ , thus  $\mathcal{M} \models (y:\exists R.\theta)$ . (IH, Definition)

case  $y:\psi = y:\forall R.\theta$  Let  $\langle \llbracket y \rrbracket, v \rangle \in \llbracket R \rrbracket$  for some  $r \in \mathcal{D}$

then  $v = z$  for some variable  $z$  with  $y R z \in B$  (construction of  $\llbracket R \rrbracket$ )

So  $z:\theta \in B$  and  $\mathcal{M} \models (z:\theta)$ . ( $\mathcal{T}_{\forall}$ -rule, saturation, Def)

As  $v$  was arbitrary we have  $\mathcal{M} \models (y:\forall R.\theta)$ .

Michael Kohlhase: Artificial Intelligence 1

521

2024-02-08

### Termination

▷ **Theorem 16.3.38.**  $\mathcal{T}_{ALC}$  terminates.

▷ To prove **termination** of a **tableau algorithm**, find a well-founded measure (function) that is decreased by all rules

$$\frac{x:c}{\perp} \mathcal{T}_{\perp} \quad \frac{x:\varphi \sqcap \psi}{x:\varphi} \mathcal{T}_{\sqcap} \quad \frac{x:\varphi \sqcup \psi}{x:\varphi \mid x:\psi} \mathcal{T}_{\sqcup} \quad \frac{x:\forall R.\varphi}{x R y \quad y:\varphi} \mathcal{T}_{\forall} \quad \frac{x:\exists R.\varphi}{x R y \quad y:\varphi} \mathcal{T}_{\exists}$$

▷ *Proof:* Sketch (full proof very technical)

1. Any rule except  $\mathcal{T}_{\forall}$  can only be applied once to  $x:\psi$ .
2. Rule  $\mathcal{T}_{\forall}$  applicable to  $x:\forall R.\psi$  at most as the number of R-successors of  $x$ . (those  $y$  with  $x R y$  above)
3. The R-successors are generated by  $x:\exists R.\theta$  above, (number bounded by size of input formula)
4. Every rule application to  $x:\psi$  generates constraints  $z:\psi'$ , where  $\psi'$  a proper sub-formula of  $\psi$ .

Michael Kohlhase: Artificial Intelligence 1

522

2024-02-08

We can turn the **termination** result into a worst-case **complexity** result by examining the sizes of **branches**.

### Complexity of $\mathcal{T}_{ALC}$

▷ **Idea:** Work off **tableau branches** one after the other. (Branch size  $\hat{=}$  space complexity)

▷ **Observation 16.3.39.** The size of the **branches** is **polynomial** in the size of the **input formula**:

$$\text{branchsize} = \#(\text{input formulae}) + \#(\exists\text{-formulae}) \cdot \#(\forall\text{-formulae})$$

▷ *Proof sketch:* Re-examine the **termination proof** and count: the first **summand** comes from Proof step 4., the second one from Proof step 3. and Proof step 2.

Michael Kohlhase: Artificial Intelligence 1

522

2024-02-08

- ▷ **Theorem 16.3.40.** The *satisfiability* problem for  $\mathcal{ALC}$  is in **PSPACE**.
- ▷ **Theorem 16.3.41.** The *satisfiability* problem for  $\mathcal{ALC}$  is **PSPACE-Complete**.
- ▷ *Proof sketch:* Reduce a **PSPACE**-complete problem to  $\mathcal{ALC}$ -satisfiability
- ▷ **Theorem 16.3.42 (Time Complexity).** The  $\mathcal{ALC}$  *satisfiability* problem is in **EXPTIME**.
- ▷ *Proof sketch:* There can be exponentially many **branches** (already for  $\text{PL}^0$ )

In summary, the theoretical **complexity** of  $\mathcal{ALC}$  is the same as that for  $\text{PL}^0$ , but in practice  $\mathcal{ALC}$  is much more expressive. So this is a clear win.

But the description of the **tableau algorithm**  $\mathcal{T}_{\mathcal{ALC}}$  is still quite abstract, so we look at an exemplary **implementation** in a **functional programming language**.

### The functional Algorithm for $\mathcal{ALC}$

- ▷ **Observation:** (leads to a better treatment for  $\exists$ )
  - ▷ the  $\mathcal{T}_{\exists}$ -rule generates the constraints  $x R y$  and  $y:\psi$  from  $x:\exists R.\psi$
  - ▷ this triggers the  $\mathcal{T}_{\forall}$ -rule for  $x:\forall R.\theta_i$ , which generate  $y:\theta_1, \dots, y:\theta_n$
  - ▷ for  $y$  we have  $y:\psi$  and  $y:\theta_1, \dots, y:\theta_n$ . (do all of this in a single step)
  - ▷ we are only interested in non-emptiness, not in particular witnesses (leave them out)

- ▷ **Definition 16.3.43.** The **functional algorithm** for  $\mathcal{T}_{\mathcal{ALC}}$  is

```

consistent(S) =
 if {c, \bar{c} } $\subseteq S$ then false
 elif ' $\varphi \sqcap \psi' \in S$ and (' $\varphi' \notin S$ or ' $\psi' \notin S$)
 then consistent($S \cup \{\varphi, \psi\}$)
 elif ' $\varphi \sqcup \psi' \in S$ and $\{\varphi, \psi\} \notin S$
 then consistent($S \cup \{\varphi\}$) or consistent($S \cup \{\psi\}$)
 elif forall ' $\exists R.\psi' \in S$
 consistent($\{\psi\} \cup \{\theta \in \theta \mid \forall R.\theta' \in S\}$)
 else true

```

- ▷ Relatively simple to **implement**. (good implementations optimized)
- ▷ **But:** This is restricted to  $\mathcal{ALC}$ . (extension to other DL difficult)

Note that we have (so far) only considered an empty **TBox**: we have initialized the **tableau** with a normalized **concept**; so we did not need to include the **concept definitions**. To cover “real” **ontologies**, we need to consider the case of **concept axioms** as well.

We now extend  $\mathcal{T}_{\mathcal{ALC}}$  with **concept axioms**. The key idea here is to realize that the **concept axioms** apply to all individuals. As the individuals are generated by the  $\mathcal{T}_{\exists}$  rule, we can simply extend that rule to apply all the **concept axioms** to the newly introduced individual.

### Extending the Tableau Algorithm by Concept Axioms

- ▷ **concept axioms**, e.g.  $\text{child} \sqsubseteq \text{son} \sqcup \text{daughter}$  cannot be handled in  $\mathcal{T}_{\text{ALC}}$  yet.
- ▷ **Idea:** Whenever a new variable  $y$  is introduced (by  $\mathcal{T}_{\exists}$ -rule) add the information that axioms hold for  $y$ .
  - ▷ Initialize tableau with  $\{x:\varphi\} \cup \mathcal{CA}$  ( $\mathcal{CA}$ : = set of concept axioms)
  - ▷ New rule for  $\exists$ :  $\frac{x:\exists R.\varphi \quad \mathcal{CA} = \{\alpha_1, \dots, \alpha_n\}}{\begin{array}{l} y:\varphi \\ x R y \\ y:\alpha_1 \\ \vdots \\ y:\alpha_n \end{array}} \mathcal{T}_{\mathcal{CA}}^{\exists}$  (instead of  $\mathcal{T}_{\exists}$ )
- ▷ **Problem:**  $\mathcal{CA} := \{\exists R.c\}$  and start tableau with  $x:d$  (non-termination)

Michael Kohlhase: Artificial Intelligence 1
525
2024-02-08

The problem of this approach is that it spoils **termination**, since we cannot control the number of **rule** applications by (fixed) properties of the input **formulae**. The example shows this very nicely. We only sketch a path towards a solution.

### Non-Termination of $\mathcal{T}_{\text{ALC}}$ with Concept Axioms

- ▷ **Problem:**  $\mathcal{CA} := \{\exists R.c\}$  and start tableau with  $x:d$ . (non-termination)

|                   |                                        |
|-------------------|----------------------------------------|
| $x:d$             | start                                  |
| $x:\exists R.c$   | in $\mathcal{CA}$                      |
| $x R y_1$         | $\mathcal{T}_{\exists}$                |
| $y_1:c$           | $\mathcal{T}_{\exists}$                |
| $y_1:\exists R.c$ | $\mathcal{T}_{\mathcal{CA}}^{\exists}$ |
| $y_1 R y_2$       | $\mathcal{T}_{\exists}$                |
| $y_2:c$           | $\mathcal{T}_{\exists}$                |
| $y_2:\exists R.c$ | $\mathcal{T}_{\mathcal{CA}}^{\exists}$ |
| ...               |                                        |

**Solution: Loop-Check:**

- ▷ Instead of a new variable  $y$  take an old variable  $z$ , if we can guarantee that whatever holds for  $y$  already holds for  $z$ .
- ▷ We can only do this, iff the  $\mathcal{T}_{\forall}$ -rule has been exhaustively applied.

- ▷ **Theorem 16.3.44.** *The consistency problem of  $\text{ALC}$  with **concept axioms** is **decidable**.*

*Proof sketch:*  $\mathcal{T}_{\text{ALC}}$  with a suitable loop check **terminates**.

### 16.3.3 ABoxes, Instance Testing, and ALC

**A Video Nugget** covering this subsection can be found at <https://fau.tv/clip/id/27303>.

Now that we have a **decision problem** for  $\text{ALC}$  with **concept axioms**, we can go the final step to the general case of **inference** in description logics: we add an **ABox** with assertional axioms that describe the individuals.

We will now extend the **description logic**  $\text{ALC}$  with assertions that

### ▷ Instance Test: Concept Membership

▷ **Definition 16.3.45.** An **instance test** computes whether given an  $\mathcal{ALC}$  ontology an **individual** is a **member** of a given **concept**.

▷ **Example 16.3.46 (An Ontology).**

| TBox (terminological Box) |                         | ABox (assertional Box, data base) |                    |
|---------------------------|-------------------------|-----------------------------------|--------------------|
| woman                     | = person $\sqcap$ has_Y | tony:person                       | Tony is a person   |
| man                       | = person $\sqcap$ has_Y | tony:has_Y                        | Tony has a y-chrom |

This entails: tony:man (Tony is a man).

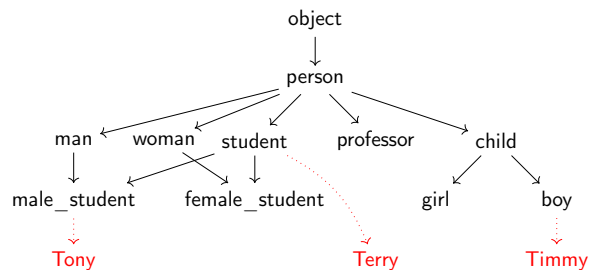

▷ **Problem:** Can we compute this?

If we combine **classification** with the **instance test**, then we get the full picture of how **concepts** and **individuals** relate to each other. We see that we get the full expressivity of **semantic networks** in  $\mathcal{ALC}$ .

### Realization

▷ **Definition 16.3.47.** **Realization** is the computation of all instance relations between **ABox** objects and **TBox** concepts.

▷ **Observation:** It is sufficient to remember the lowest **concepts** in the **subsumption graph**. (rest by subsumption)

▷ **Example 16.3.48.** If tony:male\_student is known, we do not need tony:man.

Let us now get an intuition on what kinds of interactions between the various parts of an **ontology**.

### ABox Inference in $\mathcal{ALC}$ : Phenomena

▷ There are different kinds of interactions between **TBox** and **ABox** in  $\mathcal{ALC}$  and in **description logics** in general.

▷ **Example 16.3.49.**

| property                                               | example                                                                                                                             |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| internally <b>inconsistent</b>                         | tony:student, tony:student                                                                                                          |
| <b>inconsistent</b> with a <b>TBox</b>                 | TBox: student $\sqcap$ prof<br>ABox: tony:student, tony:prof                                                                        |
| implicit info that is not explicit                     | ABox: tony: $\forall$ has_grad.genius<br>tony has_grad mary<br>$\models$ mary.genius                                                |
| information that can be combined with <b>TBox</b> info | TBox: happy_prof = prof $\sqcap$ $\forall$ has_grad.genius<br>ABox: tony:happy_prof,<br>tony has_grad mary<br>$\models$ mary.genius |

Again, we ask ourselves whether all of these are computable. Fortunately, it is very simple to add assertions to  $\mathcal{ALC}$ . In fact, we do not have to change anything, as the **judgments** used in the **tableau** are already of the form of **ABox** assertions.

### Tableau-based Instance Test and Realization

- ▷ **Query:** Do the **ABox** and **TBox** together entail  $a:\varphi$ ? ( $a \in \varphi?$ )
- ▷ **Algorithm:** Test  $a:\bar{\varphi}$  for consistency with **ABox** and **TBox**. (use our tableau algorithm)
- ▷ **Necessary changes:** (no big deal)
  - ▷ Normalize **ABox** wrt. **TBox**. (definition expansion)
  - ▷ Initialize the **tableau** with **ABox** in **NNF**. (so it can be used)
- ▷ **Example 16.3.50.**

| Example: add <b>mary:genius</b> to determine $ABox, TBox \models$ mary.genius |                                                         |                                                                                                                                                             |                                                                                                                       |
|-------------------------------------------------------------------------------|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| TBox                                                                          | happy_prof = prof $\sqcap$<br>$\forall$ has_grad.genius | tony:prof $\sqcap$ $\forall$ has_grad.genius<br>tony has_grad mary<br>mary:genius<br>tony:prof<br>tony: $\forall$ has_grad.genius<br>mary:genius<br>$\perp$ | TBox<br>ABox<br>Query<br>$\mathcal{T}_\sqcap$<br>$\mathcal{T}_\sqcap$<br>$\mathcal{T}_\forall$<br>$\mathcal{T}_\perp$ |
| ABox                                                                          | tony:happy_prof<br>tony has_grad mary                   |                                                                                                                                                             |                                                                                                                       |

- ▷ **Note:** The **instance test** is the base for **realization**. (remember?)
- ▷ **Idea:** Extend to more complex **ABox** queries. (e.g. give me all instances of  $\varphi$ )

This completes our investigation of inference for  $\mathcal{ALC}$ . We summarize that  $\mathcal{ALC}$  is a logic-based ontology language where the inference problems are all **decidable/computable** via  $\mathcal{ALC}$ . But of course, while we have reached the expressivity of basic **semantic networks**, there are still things that we cannot express in  $\mathcal{ALC}$ , so we will try to extend  $\mathcal{ALC}$  without losing **decidability/computability**.

## 16.4 Description Logics and the Semantic Web

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/27289>.

In this section we discuss how we can apply [description logics](#) in the real world, in particular, as a conceptual and [algorithmic](#) basis of the [semantic web](#). That tries to transform the [World Wide Web](#) from a human-understandable web of [multimedia](#) documents into a “web of machine-understandable data”. In this context, “machine-understandable” means that [machines](#) can draw [inferences](#) from [data](#) they have access to. Note that the discussion in this digression is not a full-blown introduction to [RDF](#) and [OWL](#), we leave that to [SR14; Her+13a; Hit+12] and the respective [W3C](#) recommendations. Instead we introduce the ideas behind the mappings from a perspective of the description logics we have discussed above.

The most important component of the [semantic web](#) is a standardized language that can represent “data” about information on the [Web](#) in a machine-oriented way.

## Resource Description Framework

- ▷ **Definition 16.4.1.** The [Resource Description Framework](#) ([RDF](#)) is a framework for describing resources on the web. It is an [XML](#) vocabulary developed by the [W3C](#).
- ▷ **Note:** [RDF](#) is designed to be read and understood by [computers](#), not to be displayed to people. (it shows)
- ▷ **Example 16.4.2.** [RDF](#) can be used for describing (all “objects on the [WWW](#)”)
  - ▷ properties for shopping items, such as price and availability
  - ▷ time schedules for web events
  - ▷ information about [web pages](#) (content, author, created and modified date)
  - ▷ content and rating for web pictures
  - ▷ content for search engines
  - ▷ electronic libraries

Note that all these examples have in common that they are about “objects on the [Web](#)”, which is an aspect we will come to now.

“Objects on the [Web](#)” are traditionally called “resources”, rather than defining them by their intrinsic properties – which would be ambitious and prone to change – we take an external property to define them: everything that has a [URI](#) is a web resource. This has repercussions on the design of [RDF](#).

## Resources and URIs

- ▷ [RDF](#) describes resources with properties and property values.
- ▷ [RDF](#) uses Web identifiers ([URIs](#)) to identify resources.
- ▷ **Definition 16.4.3.** A [resource](#) is anything that can have a [URI](#), such as `http://www.fau.de`.
- ▷ **Definition 16.4.4.** A [property](#) is a resource that has a name, such as [author](#) or [homepage](#), and a [property value](#) is the value of a property, such as [Michael Kohlhase](#) or `http://kwarc.info/kohlhase`. (a [property value](#) can be another resource)
- ▷ **Definition 16.4.5.** A [RDF statement](#)  $s$  (also known as a [triple](#)) consists of a [resource](#) (the [subject](#) of  $s$ ), a [property](#) (the [predicate](#) of  $s$ ), and a [property value](#)

(the **object** of  $s$ ). A set of **RDF triples** is called an **RDF graph**.

- ▷ **Example 16.4.6.** Statements:  $[This\ slide]^{subj}\ has\ been\ [author]^{pred}\ ed\ by\ [Michael\ Kohlhase]^{obj}$

The crucial observation here is that if we map “subjects” and “objects” to “individuals”, and “predicates” to “relations”, the **RDF** triples are just relational ABox statements of description logics. As a consequence, the techniques we developed apply.

**Note:** Actually, a **RDF graph** is technically a **labeled multigraph**, which allows multiple edges between any two nodes (the resources) and where nodes and edges are labeled by **URIs**.

We now come to the concrete syntax of **RDF**. This is a relatively conventional **XML** syntax that combines **RDF** statements with a common subject into a single “description” of that resource.

## XML Syntax for RDF

- ▷ **RDF** is a concrete **XML** vocabulary for writing statements
- ▷ **Example 16.4.7.** The following **RDF** document could describe the slides as a resource

```
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
 xmlns:dc="http://purl.org/dc/elements/1.1/">
 <rdf:Description about="https://.../CompLog/kr/en/rdf.tex">
 <dc:creator>Michael Kohlhase</dc:creator>
 <dc:source>http://www.w3schools.com/rdf</dc:source>
 </rdf:Description>
</rdf:RDF>
```

This **RDF** document makes two statements:

- ▷ The subject of both is given in the **about** attribute of the **rdf:Description** element
- ▷ The **predicates** are given by the element names of its **children**
- ▷ The **objects** are given in the elements as **URIs** or **literal** content.
- ▷ **Intuitively:** **RDF** is a web-scalable way to write down **ABox** information.

Note that **XML** namespaces play a crucial role in using element to encode the **predicate URIs**. Recall that an element name is a qualified name that consists of a **namespace URI** and a proper element name (without a colon character). Concatenating them gives a **URI** in our example the predicate **URI** induced by the **dc:creator** element is **http://purl.org/dc/elements/1.1/creator**. Note that as **URIs** go **RDF URIs** do not have to be **URLs**, but this one is and it references (is redirected to) the relevant part of the Dublin Core elements specification [DCM12].

**RDF** was deliberately designed as a standoff markup format, where **URIs** are used to annotate web resources by pointing to them, so that it can be used to give information about web resources without having to change them. But this also creates maintenance problems, since web resources may change or be deleted without warning.

**RDFa** gives authors a way to embed **RDF** triples into web resources and make keeping **RDF** statements about them more in sync.

## RDFa as an Inline RDF Markup Format

- ▷ **Problem:** RDF is a standoff markup format (annotate by URIs pointing into other files)

**Definition 16.4.8.** **RDFa** (RDF annotations) is a markup scheme for inline annotation (as XML attributes) of RDF triples.

- ▷ **Example 16.4.9.**

```
<div xmlns:dc="http://purl.org/dc/elements/1.1/" id="address">
 <h2 about="#address" property="dc:title">RDF as an Inline RDF Markup Format</h2>
 <h3 about="#address" property="dc:creator">Michael Kohlhase</h3>
 <em about="#address" property="dc:date" datatype="xsd:date"
 content="2009-11-11">November 11., 2009
</div>
```

In the example above, the `about` and `property` attributes are reserved by **RDFa** and specify the **subject** and **predicate** of the **RDF statement**. The **object** consists of the body of the element, unless otherwise specified e.g. by the `content` and `datatype` attributes for **literals** content. Let us now come back to the fact that **RDF** is just an **XML** syntax for **ABox** statements.

## RDF as an ABox Language for the Semantic Web

- ▷ **Idea:** RDF triples are ABox entries  $h R s$  or  $h:\varphi$ .

- ▷ **Example 16.4.10.**  $h$  is the resource for Ian Horrocks,  $s$  is the resource for Ulrike Sattler,  $R$  is the relation “hasColleague”, and  $\varphi$  is the class `foaf:Person`

```
<rdf:Description about="some.uri/person/ian_horrocks">
 <rdf:type rdf:resource="http://xmlns.com/foaf/0.1/Person"/>
 <hasColleague resource="some.uri/person/uli_sattler"/>
</rdf:Description>
```

- ▷ **Idea:** Now, we need a similar language for TBoxes (based on *ACL*)

In this situation, we want a standardized representation language for TBox information; **OWL** does just that: it standardizes a set of knowledge representation primitives and specifies a variety of concrete syntaxes for them. **OWL** is designed to be compatible with **RDF**, so that the two together can form an ontology language for the web.

## OWL as an Ontology Language for the Semantic Web

- ▷ **Task:** Complement **RDF** (**ABox**) with a **TBox** language.
- ▷ **Idea:** Make use of resources that are values in `rdf:type`. (called **Classes**)
- ▷ **Definition 16.4.11.** **OWL** (the **ontology web language**) is a language for encoding **TBox** information about **RDF** classes.
- ▷ **Example 16.4.12 (A concept definition for “Mother”).**  $\text{Mother} = \text{Woman} \sqcap \text{Parent}$  is represented as

XML Syntax	Functional Syntax
<code>&lt;EquivalentClasses&gt;</code>	<code>EquivalentClasses(</code>
<code>&lt;Class IRI="Mother"/&gt;</code>	<code>:Mother</code>
<code>&lt;ObjectIntersectionOf&gt;</code>	<code>ObjectIntersectionOf(</code>
<code>&lt;Class IRI="Woman"/&gt;</code>	<code>:Woman</code>
<code>&lt;Class IRI="Parent"/&gt;</code>	<code>:Parent</code>
<code>&lt;/ObjectIntersectionOf&gt;</code>	<code>)</code>
<code>&lt;/EquivalentClasses&gt;</code>	<code>)</code>

But there are also other syntaxes in regular use. We show the **functional syntax** which is inspired by the **mathematical** notation of relations.

### Extended OWL Example in Functional Syntax

- ▷ **Example 16.4.13.** The **semantic network** from Example 16.1.5 can be expressed in **OWL** (in **functional syntax**)

```

ClassAssertion (:Jack :robin)
ClassAssertion (:John :person)
ClassAssertion (:Mary :person)
ObjectPropertyAssertion (:loves :John :Mary)
ObjectPropertyAssertion (:owner_of :John :Jack)
SubClassOf (:robin :bird)
SubClassOf (:bird ObjectSomeValuesFrom (:hasPart :wing))

```

- ▷ `ClassAssertion` formalizes the “inst” relation,
- ▷ `ObjectPropertyAssertion` formalizes **relations**,
- ▷ `SubClassOf` formalizes the “isa” relation,
- ▷ for the “has\_part” relation, we have to specify that *all birds have a part that is a wing* or equivalently *the class of birds is a subclass of all objects that have some wing*.

We have introduced the ideas behind using description logics as the basis of a “machine-oriented web of data”. While the first **OWL** specification (2004) had three sublanguages “OWL Lite”, “OWL DL” and “OWL Full”, of which only the middle was based on description logics, with the OWL2 Recommendation from 2009, the foundation in description logics was nearly universally accepted.

The **semantic web** hype is by now nearly over, the technology has reached the “plateau of productivity” with many applications being pursued in academia and industry. We will not go into these, but briefly introduce one of the tools that make this work.

## SPARQL an RDF Query language

- ▷ **Definition 16.4.14.** **SPARQL**, the “**SPARQL** Protocol and **RDF** Query Language” is an **RDF query language**, able to retrieve and manipulate **data** stored in **RDF**. The **SPARQL** language was standardized by the World Wide Web Consortium in 2008 [PS08].
- ▷ **SPARQL** is pronounced like the word “*sparkle*”.
- ▷ **Definition 16.4.15.** A system is called a **SPARQL endpoint**, iff it answers **SPARQL queries**.
- ▷ **Example 16.4.16.** **Query** for person names and their e-mails from a **triplestore** with FOAF data.

```

PREFIX foaf: <http://xmlns.com/foaf/0.1/>
SELECT ?name ?email
WHERE {
 ?person a foaf:Person.
 ?person foaf:name ?name.
 ?person foaf:mbox ?email.
}

```

**SPARQL** end-points can be used to build interesting applications, if fed with the appropriate data. An interesting – and by now paradigmatic – example is the DBPedia project, which builds a large ontology by analyzing Wikipedia fact boxes. These are in a standard **HTML** form which can be analyzed e.g. by regular expressions, and their entries are essentially already in triple form: The **subject** is the Wikipedia page they are on, the **predicate** is the key, and the object is either the **URI** on the object value (if it carries a link) or the value itself.

## SPARQL Applications: DBPedia

▷ **Typical Application:** DBPedia screen-scrapes Wikipedia fact boxes for **RDF** triples and uses **SPARQL** for **querying** the induced **triplestore**.

▷ **Example 16.4.17 (DBPedia Query).** People who were born in Erlangen before 1900 (<http://dbpedia.org/snorql>)

```
SELECT ?name ?birth ?death ?person WHERE {
 ?person dbo:birthPlace :Erlangen .
 ?person dbo:birthDate ?birth .
 ?person foaf:name ?name .
 ?person dbo:deathDate ?death .
 FILTER (?birth < "1900-01-01" ^ ^xsd:date) .
}
ORDER BY ?name
```

▷ The answers include Emmy Noether and Georg Simon Ohm.

**Emmy Noether**

**Born** Amalie Emmy Noether  
23 March 1882  
Erlangen, Bavaria, German Empire

**Died** 14 April 1935 (aged 53)  
Bryn Mawr, Pennsylvania, United States

**Nationality** German

**Alma mater** University of Erlangen

**Known for** Abstract algebra  
Theoretical physics  
Noether's theorem

## A more complex DBPedia Query

▷ **Demo:** DBPedia <http://dbpedia.org/snorql/>

**Query:** Soccer players born in a country with more than 10 M inhabitants, who play as goalie in a club that has a stadium with more than 30.000 seats.

**Answer:** computed by DBPedia from a **SPARQL query**

```
SELECT distinct ?soccerplayer ?countryOfBirth ?team ?countryOfTeam ?stadiumcapacity
{
 ?soccerplayer a dbo:SoccerPlayer ;
 dbo:position|dbp:position <http://dbpedia.org/resource/Goalkeeper_(association_football)> ;
 dbo:birthPlace|dbo:country* ?countryOfBirth ;
 #dbo:number 13 ;
 dbo:team ?team .
 ?team dbo:capacity ?stadiumcapacity ; dbo:ground ?countryOfTeam .
 ?countryOfBirth a dbo:Country ; dbo:populationTotal ?population .
 ?countryOfTeam a dbo:Country .
}
FILTER (?countryOfTeam != ?countryOfBirth)
FILTER (?stadiumcapacity > 30000)
FILTER (?population > 10000000)
} order by ?soccerplayer
```

Results:

We conclude our survey of the [semantic web technology stack](#) with the notion of a [triplestore](#), which refers to the [database](#) component, which stores vast collections of [ABox triples](#).

## Triple Stores: the Semantic Web Databases

- ▷ **Definition 16.4.18.** A [triplestore](#) or [RDF store](#) is a purpose-built database for the storage [RDF graphs](#) and retrieval of [RDF triples](#) usually through variants of [SPARQL](#).
- ▷ Common [triplestores](#) include
  - ▷ Virtuoso: <https://virtuoso.openlinksw.com/> (used in DBpedia)
  - ▷ GraphDB: <http://graphdb.ontotext.com/> (often used in WissKI)
  - ▷ blazegraph: <https://blazegraph.com/> (open source; used in WikiData)
- ▷ **Definition 16.4.19.** A [description logic reasoner](#) implements of reasoning services based on a satisfiability test for [description logics](#).
- ▷ Common [description logic reasoners](#) include
  - ▷ FACT++: <http://owl.man.ac.uk/factplusplus/>
  - ▷ Hermit: <http://www.hermit-reasoner.com/>
- ▷ **Intuition:** [Triplestores](#) concentrate on [querying](#) very large [ABoxes](#) with partial consideration of the [TBox](#), while [DL reasoners](#) concentrate on the full set of ontology inference services, but fail on large [ABoxes](#).

Part IV

Planning & Acting

This part covers the [AI](#) subfield of “planning”, i.e. search-based problem solving with a [structured](#) representation language for environment [state](#) and [actions](#) — in planning, the focus is on the latter.

We first introduce the framework of planning (structured representation languages for [problems](#) and [actions](#)) and then present [algorithms](#) and [complexity](#) results. Finally, we lift some of the simplifying assumptions – [deterministic, fully observable environments](#) – we made in the previous parts of the course.

# Chapter 17

## Planning I: Framework

### Reminder: Classical Search Problems

- ▷ Example 17.0.1 (Solitaire as a Search Problem).

- ▷ **States:** Card positions (e.g. `position_Jspades=Qhearts`).
- ▷ **Actions:** Card moves (e.g. `move_Jspades_Qhearts_freecell4`).
- ▷ **Initial state:** Start configuration.
- ▷ **Goal states:** All cards “home”.
- ▷ **Solutions:** Card moves solving this game.

### Planning

- ▷ **Ambition:** Write one program that can solve all classical [search problems](#).
- ▷ **Idea:** For [CSP](#), going from “state/action-level search” to “problem-description level search” did the trick.
- ▷ **Definition 17.0.2.** Let  $\Pi$  be a [search problem](#) (see chapter 6)
  - ▷ The [blackbox description](#) of  $\Pi$  is an [API](#) providing functionality allowing to construct the state space: `InitialState()`, `GoalTest(s)`, ...

- ▷ “Specifying the problem”  $\hat{=}$  programming the API.
- ▷ The declarative description of  $\Pi$  comes in a problem description language. This allows to implement the API, and much more.
  - ▷ “Specifying the problem”  $\hat{=}$  writing a problem description.
- ▷ Here, “problem description language”  $\hat{=}$  planning language. (up next)
- ▷ **But Wait:** Didn’t we do this already in the last chapter with logics? (For the Wumpus?)

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 543 2024-02-08 

## 17.1 Logic-Based Planning

Before we go into the planning framework and its particular methods, let us see what we would do with the methods from ?? if we were to develop a “logic-based language” for describing states and actions. We will use the Wumpus world from section 10.1 as a running example.

### Fluents: Time-Dependent Knowledge in Planning

- ▷ **Recall from section 10.1:** We can represent the Wumpus rules in logical systems. (propositional/first-order/ALC)
  - ▷ Use inference systems to deduce new world knowledge from percepts and actions.
- ▷ **Problem:** Representing (changing) percepts immediately leads to contradictions!
- ▷ **Example 17.1.1.** If the agent moves and a cell with a draft (a perceived breeze) is followed by one without.
- ▷ **Obvious Idea:** Make representations of percepts time-dependent
- ▷ **Example 17.1.2.**  $D^t$  for  $t \in \mathbb{N}$  for  $PL^0$  and  $draft(t)$  in  $PL^1$  and  $PE^q$ .
- ▷ **Definition 17.1.3.** We use the word fluent to refer an aspect of the world that changes, all others we call atemporal.

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 544 2024-02-08 

Let us recall the agent-based setting we were using for the inference procedures from ?. We will elaborate this further in this section.

### Recap: Logic-Based Agents

- ▷ **Recall:** A model-based agent uses inference to model the environment, percepts, and actions.

```

function KB-AGENT (percept) returns an action
 persistent: KB, a knowledge base
 t, a counter, initially 0, indicating time
 TELL(KB, MAKE-PERCEPT-SENTENCE(percept,t))
 action := ASK(KB, MAKE-ACTION-QUERY(t))
 TELL(KB, MAKE-ACTION-SENTENCE(action,t))
 t := t+1
 return action

```

▷ **Still Unspecified:** (up next)

- ▷ MAKE-PERCEPT-SENTENCE: the effects of **percepts**.
- ▷ MAKE-ACTION-QUERY: what is the best next **action**?
- ▷ MAKE-ACTION-SENTENCE: the effects of that **action**.

In particular, we will look at the effect of time/change. (neglected so far)

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 545 2024-02-08

Now that we have the notion of **fluents** to represent the **percepts** at a given time point, let us try to model how they influence the **agent's** world model.

### Fluents: Modeling the Agent's Sensors

- ▷ **Idea:** Relate **percept fluents** to **atemporal** cell attributes.
- ▷ **Example 17.1.4.** E.g., if the **agent** perceives a **draft** at time *t*, when it is in cell [*x, y*], then there must be a **breeze** there:
 
$$\forall t, x, y. Ag@(t, x, y) \Rightarrow draft(t) \Leftrightarrow breeze(x, y)$$
- ▷ **Axioms** like these model the **agent's sensors** – here that they are totally reliable: there is a **breeze**, iff the **agent** feels a **draft**.
- ▷ **Definition 17.1.5.** We call **fluents** that describe the **agent's sensors** **sensor axioms**.
- ▷ **Problem:** Where do **fluents** like  $Ag@(t, x, y)$  come from?

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 546 2024-02-08

You may have noticed that for the **sensor axioms** we have only used **first-order logic**. There is a general story to tell here: If we have **finite domains** (as we do in the Wumpus cave) we can always “compile **first-order logic** into **propositional logic**”; if **domains** are **infinite**, we usually cannot.

We will develop this here before we go on with the Wumpus models.

## Digression: Fluents and Finite Temporal Domains

- ▷ **Observation:** Fluents like  $\forall t, x, y. \text{Ag}@ (t, x, y) \Rightarrow \text{draft}(t) \Leftrightarrow \text{breeze}(x, y)$  from Example 17.1.4 are best represented in **first-order logic**. In  $\text{PL}^0$  and  $\text{PE}^q$  we would have to use concrete instances like  $\text{Ag}@ (7, 2, 1) \Rightarrow \text{draft}(7) \Leftrightarrow \text{breeze}(2, 1)$  for all suitable  $t, x$ , and  $y$ .
- ▷ **Problem:** Unless we restrict ourselves to **finite** domains and an **end time**  $t_{\text{end}}$  we have **infinitely** many **axioms**. Even then, formalization in  $\text{PL}^0$  and  $\text{PE}^q$  is very tedious.
- ▷ **Solution:** Formalize in **first-order logic** and then compile down:
  1. enumerate ranges of **bound variables**, instantiate body, ( $\rightsquigarrow \text{PE}^q$ )
  2. translate  $\text{PE}^q$  atoms to **propositional variables**. ( $\rightsquigarrow \text{PL}^0$ )
- ▷ **In Practice:** The choice of domain, **end time**, and logic is up to **agent** designer, weighing expressivity vs. **efficiency** of inference.
- ▷ **WLOG:** We will use  $\text{PL}^1$  in the following. (**easier to read**)

We now continue to our **logic-based agent** models: Now we focus on **effect axioms** to model the effects of an **agent's actions**.

## Fluents: Effect Axioms for the Transition Model

- ▷ **Problem:** Where do **fluents** like  $\text{Ag}@ (t, x, y)$  come from?
- ▷ **Thus:** We also need **fluents** to keep track of the **agent's actions**. (**The transition model of the underlying search problem**).
- ▷ **Idea:** We also use **fluents** for the representation of **actions**.
- ▷ **Example 17.1.6.** The **action** of “going forward” at time  $t$  is captured by the **fluent**  $\text{forw}(t)$ .
- ▷ **Definition 17.1.7.** **Effect axioms** describe how the **environment** changes under an **agent's actions**.
- ▷ **Example 17.1.8.** If the **agent** is in **cell**  $[1, 1]$  **facing east** at time 0 and goes **forward**, she is in **cell**  $[2, 1]$  and no longer in  $[1, 1]$ :

$$\text{Ag}@ (0, 1, 1) \wedge \text{faceeast}(0) \wedge \text{forw}(0) \Rightarrow \text{Ag}@ (1, 2, 1) \wedge \neg \text{Ag}@ (1, 1, 1)$$

Generally: (**barring exceptions for domain border cells**)

$$\forall t, x, y. \text{Ag}@ (t, x, y) \wedge \text{faceeast}(t) \wedge \text{forw}(t) \Rightarrow \text{Ag}@ (t+1, x+1, y) \wedge \neg \text{Ag}@ (t+1, x, y)$$

This compiles down to  $16 \cdot t_{\text{end}} \text{PE}^q / \text{PL}^0$  axioms.

Unfortunately, the **percept fluents**, **sensor axioms**, and **effect axioms** are not enough, as we will show in Example 17.1.9. We will see that this is a more general problem – the famous **frame**

problem that needs to be considered whenever we deal with change in environments.

## Frames and Frame Axioms

- ▷ **Problem:** Effect axioms are not enough.
- ▷ **Example 17.1.9.** Say that the agent has an arrow at time 0, and then moves forward into [2, 1], perceives a glitter, and knows that the Wumpus is ahead.  
To evaluate the action `shoot(1)` the corresponding effect axiom needs to know `havarrow(1)`, but cannot prove it from `havarrow(0)`.  
**Problem:** The information of having an arrow has been lost in the move forward.
- ▷ **Definition 17.1.10.** The frame problem describes that for a representation of actions we need to formalize their effects on the aspects they change, but also their non-effect on the static frame of reference.
- ▷ **Partial Solution:** (there are many many more; some better)  
Frame axioms formalize that particular fluents are invariant under a given action.
- ▷ **Problem:** For an agent with  $n$  actions and an environment with  $m$  fluents, we need  $\mathcal{O}(nm)$  frame axioms.  
Representing and reasoning with them easily drowns out the sensor and transition models.

We conclude our discussion with a relatively complete implementation of a logic-based Wumpus agent, building on the schema from slide 545.

## A Hybrid Agent for the Wumpus World

- ▷ **Example 17.1.11 (A Hybrid Agent).** This agent uses
  - ▷ logic inference for sensor and transition modeling,
  - ▷ special code and  $A^*$  for action selection & route planning.

**function** HYBRID-WUMPUS-AGENT(*percept*) **returns** an action

**inputs:** *percept*, a list, [stench,breeze,glitter,bump,scream]

**persistent:**  $KB$ , a knowledge base, initially the atemporal

"wumpus physics"

$t$ , a counter, initially 0, indicating time

*plan*, an action sequence, initially empty

TELL( $KB$ , MAKE-PERCEPT-SENTENCE(*percept*, $t$ ))

then some special code for action selection, and then

(up next)

*action* := POP(*plan*)

TELL( $KB$ , MAKE-ACTION-SENTENCE(*action*, $t$ ))

$t$  :=  $t + 1$

**return** *action*

So far, not much new over our original version.

Now look at the “special code” we have promised.

## A Hybrid Agent: Custom Action Selection

- ▷ **Example 17.1.12 (A Hybrid Agent (continued)).** So that we can plan the best strategy:

```

TELL(KB, the temporal "physics" sentences for time t)
safe := {[x, y]ASK(KB,OK(t,x,y))=T}
if ASK(KB,glitter(t)) = T then
 plan := [grab] + PLAN-ROUTE(current,{[1, 1]},safe) + [exit]
if plan is empty then
 unvisited := {[x, y]ASK(KB,Ag@(t',x,y))=F} for all t' ≤ t
 plan := PLAN-ROUTE(current,unvisited ∪ safe,safe)
if plan is empty and ASK(KB,havarrow(t)) = T then
 possible_wumpus := {x, y|x, y}ASK(KB,¬wumpus(t,x,y)) = F
 plan := PLAN-SHOT(current,possible_wumpus,safe)
if plan is empty then // no choice but to take a risk
 not_unsafe := {[x, y]ASK(KB,¬OK(t,x,y)) = F}
 plan := PLAN-ROUTE(current,unvisited ∪ not_unsafe,safe)
if plan is empty then
 plan := PLAN-ROUTE(current,{[1, 1]},safe) + [exit]

```

Note that `OK wumpus`, and `glitter` are **fluents**, since the Wumpus might have died or the gold might have been **grabbed**.

And finally the route planning part of the code. This is essentially just  $A^*$  search.

## A Hybrid Agent: Custom Action Selection

- ▷ **Example 17.1.13 (Action Selection).** And the `code` for PLAN-ROUTE (PLAN-SHOT similar)

```

function PLAN-ROUTE(curr,goals,allowed) returns an action sequence
 inputs: curr, the agent's current position
 goals, a set of squares;
 try to plan a route to one of them
 allowed, a set of squares that can form part of the route
 problem := ROUTE-PROBLEM(curr,goals,allowed)
 return A*(problem)

```

- ▷ **Evaluation:** Even though this works for the Wumpus world, it is not the “universal, logic-based problem solver” we dreamed of!
- ▷ Planning tries to solve this with another representation of **actions**. (up next)

## 17.2 Planning: Introduction

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/26892>.

### How does a planning language describe a problem?

▷ **Definition 17.2.1.** A **planning language** is a way of describing the components of a **search problem** via **formulae** of a **logical system**. In particular the

- ▷ **states** (vs. blackbox: **data structures**). (E.g.: **predicate**  $Eq(.,.)$ .)
- ▷ **initial state**  $I$  (vs. **data structures**). (E.g.:  $Eq(x, 1)$ .)
- ▷ **goal states**  $G$  (vs. a **goal test**). (E.g.:  $Eq(x, 2)$ .)
- ▷ set  $A$  of **actions** in terms of **preconditions** and **effects** (vs. functions returning applicable **actions** and **successor states**). (E.g.: “**increment**  $x$ : **pre**  $Eq(x, 1)$ , **eff**  $Eq(x \wedge 2) \wedge \neg Eq(x, 1)$ ”.)

A logical description of all of these is called a **planning task**.

▷ **Definition 17.2.2.** Solution (**plan**)  $\hat{=}$  sequence of **actions** from  $\mathcal{A}$ , transforming  $\mathcal{I}$  into a **state** that satisfies  $\mathcal{G}$ . (E.g.: “**increment**  $x$ ”.)

The process of finding a **plan** given a **planning task** is called **planning**.

### Planning Language Overview

▷ **Disclaimer:** **Planning languages** go way beyond classical **search problems**. There are variants for inaccessible, stochastic, dynamic, continuous, and multi-agent settings.

▷ We focus on classical search for simplicity (and practical relevance).

▷ For a comprehensive overview, see [GNT04].

### Application: Natural Language Generation

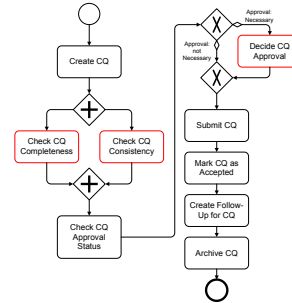

▷ **Input:** Tree-adjoining grammar, intended meaning.

▷ **Output:** Sentence expressing that meaning.

## Application: Business Process Templates at SAP

Action name	precondition	effect
Check CQ Completeness	CQ.archiving:notArchived	CQ.completeness:complete OR CQ.completeness:notComplete
Check CQ Consistency	CQ.archiving:notArchived	CQ.consistency:consistent OR CQ.consistency:notConsistent
Check CQ Approval Status	CQ.archiving:notArchived AND CQ.approval:notChecked AND CQ.completeness:complete AND CQ.consistency:consistent	CQ.approval:necessary OR CQ.approval:notNecessary
Decide CQ Approval	CQ.archiving:notArchived AND CQ.approval:necessary	CQ.approval:granted OR CQ.approval:notGranted
Submit CQ	CQ.archiving:notArchived AND (CQ.approval:notNecessary OR CQ.approval:granted)	CQ.submission:submitted
Mark CQ as Accepted	CQ.archiving:notArchived AND CQ.submission:submitted	CQ.acceptance:accepted
Create Follow-Up for CQ	CQ.archiving:notArchived AND CQ.acceptance:accepted	CQ.followUp:documentCreated
Archive CQ	CQ.archiving:notArchived	CQ.archiving:archived

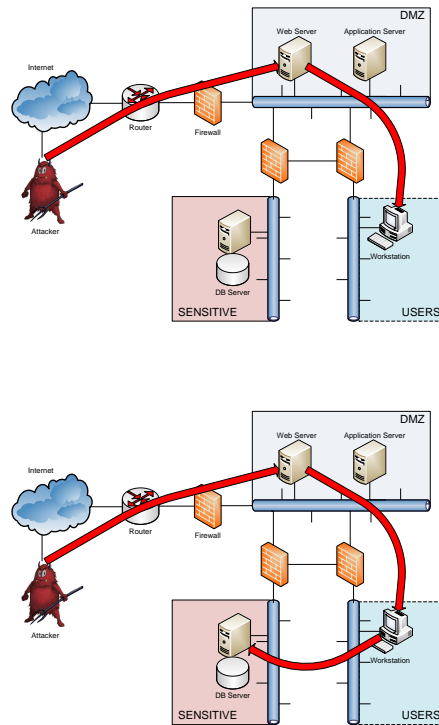

▷ **Input:** model of behavior of activities on business objects, process endpoint.

▷ **Output:** Process template leading to this point.

## Application: Automatic Hacking

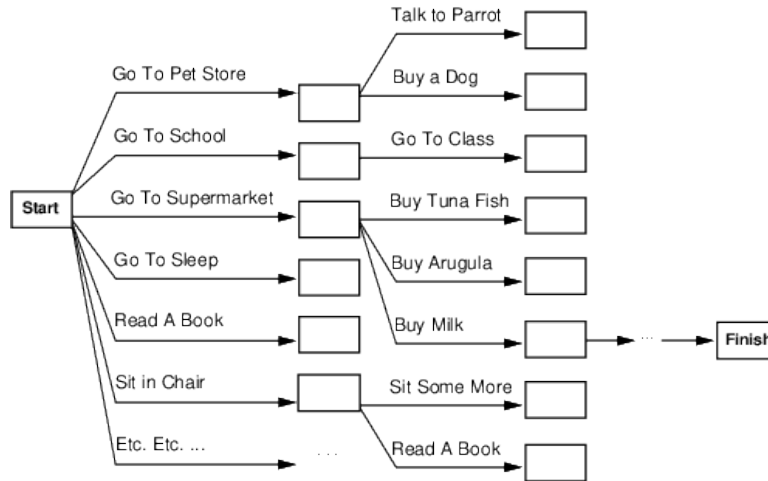

- ▷ **Input:** Network configuration, location of sensible data.
- ▷ **Output:** Sequence of exploits giving access to that data.

## Reminder: General Problem Solving, Pros and Cons

- ▷ **Powerful:** In some applications, generality is absolutely necessary. (E.g. SAP)
- ▷ **Quick:** Rapid prototyping: 10s lines of problem description vs. 1000s lines of C++ code. (E.g. language generation)
- ▷ **Flexible:** Adapt/maintain *the description*. (E.g. network security)
- ▷ **Intelligent:** Determines automatically how to solve a complex problem *efficiently!* (The ultimate goal, no?!)
- ▷ **Efficiency loss:** Without any domain-specific knowledge about *chess*, you don't beat Kasparov . . .
  - ▷ Trade-off between “automatic and general” vs. “manual work but *efficient*”.
- ▷ **Research Question:** How to make fully automatic *algorithms efficient?*

## Search vs. planning

- ▷ Consider the task *get milk, bananas, and a cordless drill*.
- ▷ Standard search algorithms seem to fail miserably:

After-the-fact heuristic/goal test inadequate

- ▷ Planning systems do the following:
  1. open up action and goal representation to allow selection
  2. divide-and-conquer by subgoaling
- ▷ relax requirement for sequential construction of solutions

	Search	Planning
<b>States</b>	Lisp data structures	Logical sentences
<b>Actions</b>	Lisp code	Preconditions/outcomes
<b>Goal</b>	Lisp code	Logical sentence (conjunction)
<b>Plan</b>	Sequence from $S_0$	Constraints on actions

## Reminder: Greedy Best-First Search and $A^*$

- ▷ **Recall:** Our heuristic search algorithms (duplicate pruning omitted for simplicity)

```

function Greedy_Best-First_Search (problem)
 returns a solution, or failure
 $n :=$ node with $n.state = problem.InitialState$
 $frontier :=$ priority queue ordered by ascending h , initially $[n]$
 loop do
 if Empty?($frontier$) then return failure
 $n :=$ Pop($frontier$)
 if problem.GoalTest($n.state$) then return Solution(n)
 for each action a in problem.Actions($n.state$) do

```

$n' := \text{ChildNode}(\text{problem}, n, a)$

$\text{Insert}(n', h(n'), \text{frontier})$

For  $A^*$

- ▷ order *frontier* by  $g + h$  instead of  $h$  (line 4)
- ▷ insert  $g(n') + h(n')$  instead of  $h(n')$  to *frontier* (last line)
- ▷ Is greedy best-first search optimal? No  $\leadsto$  **satisficing planning**.
- ▷ Is  $A^*$  optimal? Yes, but only if  $h$  is **admissible**  $\leadsto$  **optimal planning, with such  $h$** .

### ps. "Making Fully Automatic Algorithms Efficient"

▷ **Example 17.2.3.**

▷  $n$  blocks, 1 hand.

▷ A single **action** either takes a block with the hand or puts a block we're holding onto some other block/the table.

blocks	states	blocks	states
1	1	9	4596553
2	3	10	58941091
3	13	11	824073141
4	73	12	12470162233
5	501	13	202976401213
6	4051	14	3535017524403
7	37633	15	65573803186921
8	394353	16	1290434218669921

- ▷ **Observation 17.2.4.** *State spaces* typically are huge even for simple problems.
- ▷ **In other words:** Even solving "simple problems" automatically (without help from a human) requires a form of **intelligence**.
- ▷ With blind search, even the largest **super computer** in the world won't scale beyond 20 blocks!

### Algorithmic Problems in Planning

- ▷ **Definition 17.2.5.** We speak of **satisficing planning** if
  - Input:** A **planning task**  $\Pi$ .
  - Output:** A plan for  $\Pi$ , or "unsolvable" if no plan for  $\Pi$  exists.
 and of **optimal planning** if
  - Input:** A **planning task**  $\Pi$ .
  - Output:** An **optimal plan** for  $\Pi$ , or "unsolvable" if no plan for  $\Pi$  exists.
- ▷ The techniques successful for either one of these are almost **disjoint**. And **satisficing planning** is *much* more **efficient** in practice.

- ▷ **Definition 17.2.6.** Programs solving these problems are called (optimal) **planner**, **planning system**, or **planning tool**.

## Our Agenda for This Topic

---

- ▷ **Now:** Background, **planning languages**, **complexity**.
  - ▷ Sets up the framework. **Computational complexity** is essential to distinguish different **algorithmic** problems, and for the design of **heuristic functions**. (see **next**)
- ▷ **Next:** How to automatically generate a **heuristic function**, given **planning language** input?
  - ▷ Focussing on **heuristic search** as the solution method, this is the main question that needs to be answered.

## Our Agenda for This Chapter

---

1. **The History of Planning:** How did this come about?
  - ▷ Gives you some background, and motivates our choice to focus on heuristic search.
2. **The STRIPS Planning Formalism:** Which concrete planning formalism will we be using?
  - ▷ Lays the framework we'll be looking at.
3. **The PDDL Language:** What do the input files for off-the-shelf planning software look like?
  - ▷ So you can actually play around with such software. (Exercises!)
4. **Planning Complexity:** How **complex** is **planning**?
  - ▷ The price of generality is complexity, and here's what that "price" is, exactly.

## 17.3 The History of Planning

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/26894>.

### Planning History: In the Beginning ...

---

- ▷ **In the beginning:** Man invented Robots:

- ▷ “Planning” as in “the making of plans by an autonomous robot”.
- ▷ Shakey the Robot (Full video here)
- ▷ **In a little more detail:**
  - ▷ [NS63] introduced *general problem solving*.
  - ▷ ... *not much happened (well not much we still speak of today)* ...
  - ▷ 1966-72, Stanford Research Institute developed a robot named “Shakey”.
  - ▷ They needed a “planning” component taking decisions.
  - ▷ They took inspiration from general problem solving and theorem proving, and called the resulting **algorithm STRIPS**.

## History of Planning Algorithms

- ▷ **Compilation into Logics/Theorem Proving:**
  - ▷ e.g.  $\exists s_0, a, s_1. at(A, s_0) \wedge execute(s_0, a, s_1) \wedge at(B, s_1)$
  - ▷ **Popular when:** Stone Age – 1990.
  - ▷ **Approach:** From *planning task* description, generate PL1 formula  $\varphi$  that is *satisfiable iff there exists a plan*; use a theorem prover on  $\varphi$ .
  - ▷ **Keywords/cites:** Situation calculus, frame problem, ...
- ▷ **Partial order planning**
  - ▷ e.g.  $open = \{at(B)\}$ ; apply  $move(A, B)$ ;  $\rightsquigarrow open = \{at(A)\}$  ...
  - ▷ **Popular when:** 1990 – 1995.
  - ▷ **Approach:** Starting at goal, extend partially ordered set of *actions* by inserting *achievers* for open sub-goals, or by adding ordering constraints to avoid conflicts.
  - ▷ **Keywords/cites:** UCPOP [PW92], *causal links*, flaw selection strategies, ...

## History of Planning Algorithms, ctd.

- ▷ GraphPlan
  - ▷ e.g.  $F_0 = at(A)$ ;  $A_0 = \{move(A, B)\}$ ;  $F_1 = \{at(B)\}$ ;  
mutex  $A_0 = \{move(A, B), move(A, C)\}$ .
  - ▷ **Popular when:** 1995 – 2000.
  - ▷ **Approach:** In a forward phase, build a layered “planning graph” whose “time steps” capture which pairs of action can achieve which pairs of facts; in a backward phase, search this graph starting at goals and excluding options proved to not be feasible.
  - ▷ **Keywords/cites:** [BF95; BF97; Koe+97], action/fact mutexes, step-optimal plans, ...

### ▷ Planning as SAT:

- ▷ SAT variables  $at(A)_0$ ,  $at(B)_0$ ,  $move(A, B)_0$ ,  $move(A, C)_0$ ,  $at(A)_1$ ,  $at(B)_1$ ; clauses to encode transition behavior e.g.  $at(B)_1^F \vee move(A, B)_0^T$ ; unit clauses to encode initial state  $at(A)_0^T$ ,  $at(B)_0^T$ ; unit clauses to encode goal  $at(B)_1^T$ .
- ▷ **Popular when:** 1996 – today.
- ▷ **Approach:** From *planning task description*, generate propositional CNF formula  $\varphi_k$  that is *satisfiable* iff there exists a *plan* with  $k$  steps; use a *SAT solver* on  $\varphi_k$ , for different values of  $k$ .
- ▷ **Keywords/cites:** [KS92; KS98; RHN06; Rin10], SAT encoding schemes, Black-Box, ...

## History of Planning Algorithms, ctd.

### ▷ Planning as Heuristic Search:

- ▷ init  $at(A)$ ; apply  $move(A, B)$ ; generates state  $at(B)$ ; ...
- ▷ **Popular when:** 1999 – today.
- ▷ **Approach:** Devise a method  $\mathcal{R}$  to simplify (“relax”) any *planning task*  $\Pi$ ; given  $\Pi$ , solve  $\mathcal{R}(\Pi)$  to generate a *heuristic function*  $h$  for informed search.
- ▷ **Keywords/cites:** [BG99; HG00; BG01; HN01; Ede01; GSS03; Hel06; HHH07; HG08; KD09; HD09; RW10; NHH11; KHH12a; KHH12b; KHD13; DHK15], critical path heuristics, ignoring delete lists, relaxed plans, landmark heuristics, abstractions, partial delete relaxation, ...

## The International Planning Competition (IPC)

- ▷ **Definition 17.3.1.** The **International Planning Competition (IPC)** is an event for **benchmarking planners** (<http://ipc.icapsconference.org/>)
  - ▷ **How:** Run competing planners on a set of **benchmarks**.
  - ▷ **When:** Runs every two years since 2000, annually since 2014.
  - ▷ **What:** **Optimal** track vs. **satisficing** track; others: **uncertainty**, **learning**, ...
- ▷ **Prerequisite/Result:**
  - ▷ Standard representation language: **PDDL** [McD+98; FL03; HE05; Ger+09]
  - ▷ Problem Corpus:  $\approx 50$  **domains**,  $\gg 1000$  **instances**, 74 (!!) planners in 2011

## International Planning Competition

- ▷ **Question:** If planners  $x$  and  $y$  compete in IPC'YY, and  $x$  wins, is  $x$  “better than”  $y$ ?
- ▷ **Answer:** reserved for the plenary sessions  $\rightsquigarrow$  be there!
- ▷ **Generally:** reserved for the plenary sessions  $\rightsquigarrow$  be there!

## Planning History, p.s.: Planning is Non-Trivial!

- ▷ **Example 17.3.2.** The **Sussman anomaly** is a simple blockworld planning problem:

Simple planners that split the goal into subgoals  $\text{on}(A, B)$  and  $\text{on}(B, C)$  fail:

- ▷ If we pursue  $\text{on}(A, B)$  by unstacking  $C$ , and moving  $A$  onto  $B$ , we achieve the first subgoal, but cannot achieve the second without undoing the first.
- ▷ If we pursue  $\text{on}(B, C)$  by moving  $B$  onto  $C$ , we achieve the second subgoal, but cannot achieve the first without undoing the second.

## 17.4 The STRIPS Planning Formalism

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/26896>.

### STRIPS Planning

- ▷ **Definition 17.4.1.** **STRIPS** = Stanford Research Institute Problem Solver.  
*STRIPS is the simplest possible (reasonably expressive) logics based planning language.*
- ▷ STRIPS has only **propositional variables** as **atomic formulae**.
- ▷ Its **preconditions/effects/goals** are as canonical as imaginable:

- ▷ Preconditions, goals: conjunctions of atoms.
- ▷ Effects: conjunctions of literals
- ▷ We use the common special-case notation for this simple formalism.
- ▷ I'll outline some extensions beyond STRIPS later on, when we discuss PDDL.
- ▷ **Historical note:** STRIPS [FN71] was originally a planner (cf. Shakey), whose language actually wasn't quite that simple.

## STRIPS Planning: Syntax

- ▷ **Definition 17.4.2.** A STRIPS task is a quadruple  $\langle P, A, I, G \rangle$  where:
  - ▷  $P$  is a finite set of facts: atomic proposition in  $PL^0$  or  $PL^q$ .
  - ▷  $A$  is a finite set of actions; each  $a \in A$  is a triple  $a = \langle \text{pre}_a, \text{add}_a, \text{del}_a \rangle$  of subsets of  $P$  referred to as the action's preconditions, add list, and delete list respectively; we require that  $\text{add}_a \cap \text{del}_a = \emptyset$ .
  - ▷  $I \subseteq P$  is the initial state.
  - ▷  $G \subseteq P$  is the goal state.

We will often give each action  $a \in A$  a name (a string), and identify  $a$  with that name.

- ▷ **Note:** We assume, for simplicity, that every action has cost 1. (Unit costs, cf. chapter 6)

## "TSP" in Australia

- ▷ **Example 17.4.3 (Salesman Travelling in Australia).**

Strictly speaking, this is not actually a **TSP** problem instance; simplified/adapted for illustration.

## STRIPS Encoding of "TSP"

▷ **Example 17.4.4 (continuing).**

- ▷ Facts  $P$ :  $\{at(x), vis(x) | x \in \{Sy, Ad, Br, Pe, Da\}\}$ .
- ▷ Initial state  $I$ :  $\{at(Sy), vis(Sy)\}$ .
- ▷ Goal state  $G$ :  $\{at(Sy)\} \cup \{vis(x) | x \in \{Sy, Ad, Br, Pe, Da\}\}$ .
- ▷ Actions  $a \in A$ :  $drv(x, y)$  where  $x$  and  $y$  have a road.  
 Preconditions  $pre_a$ :  $\{at(x)\}$ .  
 Add list  $add_a$ :  $\{at(y), vis(y)\}$ .  
 Delete list  $del_a$ :  $\{at(x)\}$ .
- ▷ Plan:  $\langle drv(Sy, Br), drv(Br, Sy), drv(Sy, Ad), drv(Ad, Pe), drv(Pe, Ad), \dots, \dots, drv(Ad, Da), drv(Da, Ad), drv(Ad, Sy) \rangle$

## STRIPS Planning: Semantics

- ▷ **Idea:** We define a **plan** for a STRIPS task  $\Pi$  as a **solution** to an **induced search problem**  $\Theta_\Pi$ . (save work by reduction)
- ▷ **Definition 17.4.5.** Let  $\Pi := \langle P, A, I, G \rangle$  be a STRIPS task. The search problem **induced** by  $\Pi$  is  $\Theta_\Pi = \langle S_P, A, T, I, S_G \rangle$  where:
  - ▷ The **states** (also **world state**)  $S_P := \mathcal{P}(P)$  are the **subsets** of  $P$ .
  - ▷  $A$  is just  $\Pi$ 's **action**. (so we can define plans easily)
  - ▷ The **transition model**  $T_A$  is  $\{s \xrightarrow{a} apply(s, a) | pre_a \subseteq s\}$ .  
 If  $pre_a \subseteq s$ , then  $a \in A$  is **applicable** in  $s$  and  $apply(s, a) := (s \cup add_a) \setminus del_a$ . If  $pre_a \not\subseteq s$ , then  $apply(s, a)$  is **undefined**.
  - ▷  $I$  is  $\Pi$ 's **initial state**.
  - ▷ The **goal states**  $S_G = \{s \in S_P | G \subseteq s\}$  are those that satisfy  $\Pi$ 's **goal state**.

An (optimal) **plan** for  $\Pi$  is an (optimal) **solution** for  $\Theta_{\Pi}$ , i.e., a path from  $s$  to some  $s' \in S_G$ .  $\Pi$  is **solvable** if a **plan** for  $\Pi$  exists.

▷ **Definition 17.4.6.** For a **plan**  $a = \langle a_1, \dots, a_n \rangle$ , we define

$$\text{apply}(s, a) := \text{apply}(\dots \text{apply}(\text{apply}(s, a_1), a_2) \dots, a_n)$$

if each  $a_i$  is **applicable** in the respective state; else,  $\text{apply}(s, a)$  is **undefined**.

## STRIPS Encoding of Simplified TSP

▷ **Example 17.4.7 (Simplified traveling salesman problem in Australia).**

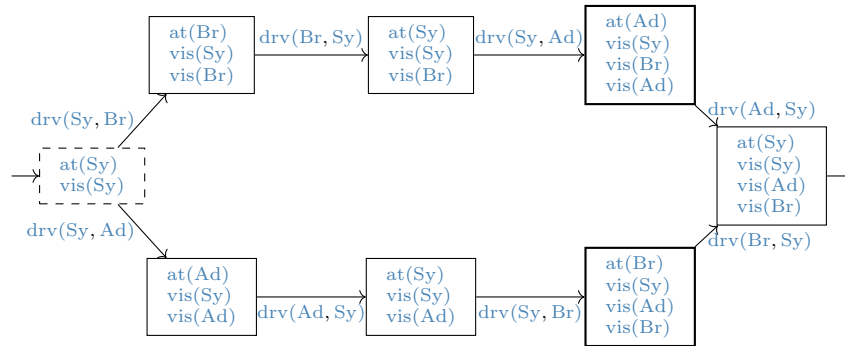

Let  $TSP_{\_}$  be the STRIPS task,  $\langle P, A, I, G \rangle$ , where

- ▷ Facts  $P$ :  $\{\text{at}(x), \text{vis}(x) \mid x \in \{\text{Sy}, \text{Ad}, \text{Br}\}\}$ .
- ▷ Initial state  $I$ :  $\{\text{at}(\text{Sy}), \text{vis}(\text{Sy})\}$ .
- ▷ Goal state  $G$ :  $\{\text{vis}(x) \mid x \in \{\text{Sy}, \text{Ad}, \text{Br}\}\}$  (note:  $\text{noat}(\text{Sy})$ )
- ▷ Actions  $A$ :  $a \in A$ :  $\text{drv}(x, y)$  where  $x, y$  have a road.
  - ▷ preconditions  $\text{pre}_a$ :  $\{\text{at}(x)\}$ .
  - ▷ add list  $\text{add}_a$ :  $\{\text{at}(y), \text{vis}(y)\}$ .
  - ▷ delete list  $\text{del}_a$ :  $\{\text{at}(x)\}$ .

## Questionnaire: State Space of $TSP_{\_}$

▷ The state space of the search problem  $\Theta_{TSP_{\_}}$  induced by  $TSP_{\_}$  from Example 17.4.7 is

- ▷ **Question:** Are there any plans for TSP<sub>-</sub> in this graph?
- ▷ **Answer:** Yes, two – plans for TSP<sub>-</sub> are solutions for  $\Theta_{TSP_-}$ , dashed node  $\hat{=}$   $I$ , thick nodes  $\hat{=}$   $G$ :
  - ▷  $drv(Sy, Br), drv(Br, Sy), drv(Sy, Ad)$  (upper path)
  - ▷  $drv(Sy, Ad), drv(Ad, Sy), drv(Sy, Br)$ . (lower path)
- ▷ **Question:** Is the graph above actually the state space induced by ?
- ▷ **Answer:** No, only the part reachable from  $I$ . The state space of  $\Theta_{TSP_-}$  also includes e.g. the states  $\{vis(Sy)\}$  and  $\{at(Sy), at(Br)\}$ .

## The Blockworld

- ▷ **Definition 17.4.8.** The **blocks world** is a simple planning domain: a set of wooden blocks of various shapes and colors sit on a table. The goal is to build one or more vertical stacks of blocks. Only one block may be moved at a time: it may either be placed on the table or placed atop another block.

- ▷ **Example 17.4.9.**

- ▷ **Facts:**  $on(x, y), onTable(x), clear(x), holding(x), armEmpty$ .
- ▷ **initial state:**  $\{onTable(E), clear(E), \dots, onTable(C), on(D, C), clear(D), armEmpty\}$ .
- ▷ **Goal state:**  $\{on(E, C), on(C, A), on(B, D)\}$ .
- ▷ **Actions:**  $stack(x, y), unstack(x, y), putdown(x), pickup(x)$ .
- ▷  $stack(x, y)?$ 
  - pre :  $\{holding(x), clear(y)\}$
  - add :  $\{on(x, y), armEmpty, clearx\}$
  - del :  $\{holding(x), clear(y)\}$ .

## STRIPS for the Blockworld

▷ **Question:** Which are correct encodings (ones that are part of **some** correct overall model) of the STRIPS Blockworld  $\text{pickup}(x)$  action schema?

- |     |                                                                                                                                                   |     |                                                                                                                                  |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------|-----|----------------------------------------------------------------------------------------------------------------------------------|
| (A) | $\{\text{onTable}(x), \text{clear}(x), \text{armEmpty}\}$<br>$\{\text{holding}(x)\}$<br>$\{\text{onTable}(x)\}$                                   | (B) | $\{\text{onTable}(x), \text{clear}(x), \text{armEmpty}\}$<br>$\{\text{holding}(x)\}$<br>$\{\text{armEmpty}\}$                    |
| (C) | $\{\text{onTable}(x), \text{clear}(x), \text{armEmpty}\}$<br>$\{\text{holding}(x)\}$<br>$\{\text{onTable}(x), \text{armEmpty}, \text{clear}(x)\}$ | (D) | $\{\text{onTable}(x), \text{clear}(x), \text{armEmpty}\}$<br>$\{\text{holding}(x)\}$<br>$\{\text{onTable}(x), \text{armEmpty}\}$ |

**Recall:** an actions  $a$  represented by a tuple  $\langle \text{pre}_a, \text{add}_a, \text{del}_a \rangle$  of lists of facts.

▷ **Hint:** The only differences between them are the delete lists

▷ **Answer:** reserved for the plenary sessions  $\rightsquigarrow$  be there!

The next example for a **planning task** is not obvious at first sight, but has been quite influential, showing that many industry problems can be specified declaratively by formalizing the domain and the particular **planning tasks** in PDDL and then using off-the-shelf **planners** to solve them. [KS00] reports that this has significantly reduced labor costs and increased maintainability of the **implementation**.

## Miconic-10: A Real-World Example

▷ **Example 17.4.10.** Elevator control as a planning problem; details at [KS00]  
Specify mobility needs before boarding, let a planner schedule/optimize trips

- ▷ VIP: Served first.
- ▷ D: Lift may only go *down* when inside; similar for U.
- ▷ NA: Never-alone
- ▷ AT: Attendant.
- ▷ A, B: Never together in the same elevator
- ▷ P: Normal passenger

## 17.5 Partial Order Planning

In this section we introduce a new and different **planning algorithm**: **partial order planning** that works on several subgoals independently without having to specify in which order they will be pursued and later combines them into a global **plan**. **A Video Nugget** covering this section can be found at <https://fau.tv/clip/id/28843>.

To fortify our intuitions about **partial order planning** let us have another look at the **Sussman anomaly**, where pursuing two subgoals independently and then reconciling them is a prerequisite.

### Planning History, p.s.: Planning is Non-Trivial!

▷ **Example 17.5.1.** The **Sussman anomaly** is a simple blocksworld planning problem:

Simple planners that split the goal into subgoals  $\text{on}(A, B)$  and  $\text{on}(B, C)$  fail:

- ▷ If we pursue  $\text{on}(A, B)$  by unstacking  $C$ , and moving  $A$  onto  $B$ , we achieve the first subgoal, but cannot achieve the second without undoing the first.
- ▷ If we pursue  $\text{on}(B, C)$  by moving  $B$  onto  $C$ , we achieve the second subgoal, but cannot achieve the first without undoing the second.

Before we go into the details, let us try to understand the main ideas of **partial order planning**.

### Partial Order Planning

▷ **Definition 17.5.2.** Any **algorithm** that can place two **actions** into a **plan** without specifying which comes first is called as **partial order planning**.

▷ **Ideas** for **partial order planning**:

- ▷ Organize the planning steps in a DAG that supports multiple paths from initial to goal state
  - ▷ nodes (steps) are labeled with **actions** (actions can occur multiply)
  - ▷ edges with propositions added by source and presupposed by target
- ▷ acyclicity of the graph induces a partial ordering on steps.  $q$
- ▷ additional temporal constraints resolve subgoal interactions and induce a linear order.

- ▷ **Advantages** of **partial order planning**:
  - ▷ problems can be decomposed  $\leadsto$  can work well with non-cooperative environments.
  - ▷ **efficient** by least-commitment strategy
  - ▷ causal links (edges) pinpoint unworkable subplans early.

We now make the ideas discussed above concrete by giving a **mathematical** formulation. It is advantageous to cast a **partially ordered plan** as a labeled DAG rather than a **partial ordering** since it draws the attention to the difference between **actions** and **steps**.

## Partially Ordered Plans

- ▷ **Definition 17.5.3.** Let  $\langle P, A, I, G \rangle$  be a STRIPS task, then a **partially ordered plan**  $\mathcal{P} = \langle V, E \rangle$  is a **labeled DAG**, where the **nodes** in  $V$  (called **steps**) are labeled with **actions** from  $A$ , or are a
  - ▷ **start step**, which has label “effect”  $I$ , or a
  - ▷ **finish step**, which has label “precondition”  $G$ .

Every edge  $(S, T) \in E$  is either **labeled** by:

- ▷ A **non-empty set**  $p \subseteq P$  of **facts** that are **effects** of the **action** of  $S$  and the **preconditions** of that of  $T$ . We call such a labeled edge a **causal link** and write it  $S \xrightarrow{p} T$ .
- ▷  $\prec$ , then call it a **temporal constraint** and write it as  $S \prec T$ .

An **open condition** is a **precondition** of a **step** not yet **causally linked**.

- ▷ **Definition 17.5.4.** Let  $\Pi$  be a **partially ordered plan**, then we call a **step**  $U$  **possibly intervening** in a **causal link**  $S \xrightarrow{p} T$ , iff  $\Pi \cup \{S \prec U, U \prec T\}$  is **acyclic**.
- ▷ **Definition 17.5.5.** A **precondition** is **achieved** iff it is the **effect** of an earlier **step** and no **possibly intervening step** undoes it.
- ▷ **Definition 17.5.6.** A **partially ordered plan**  $\Pi$  is called **complete** iff every **precondition** is **achieved**.
- ▷ **Definition 17.5.7.** **Partial order planning** is the process of computing **complete** and **acyclic partially ordered plans** for a given **planning task**.

## A Notation for STRIPS Actions

- ▷ **Definition 17.5.8 (Notation).** In diagrams, we often write STRIPS actions into boxes with **preconditions** above and **effects** below.
- ▷ **Example 17.5.9.**

- ▷ Actions:  $Buy(x)$
- ▷ Preconditions:  $At(p), Sells(p, x)$
- ▷ Effects:  $Have(x)$

$$\frac{At(p) \ Sells(p, x)}{\boxed{Buy(x)} \ Have(x)}$$

- ▷ **Notation:** A causal link  $S \xrightarrow{p} T$  can also be denoted by a direct arrow between the effects  $p$  of  $S$  and the preconditions  $p$  of  $T$  in the STRIPS action notation above.  
Show temporal constraints as dashed arrows.

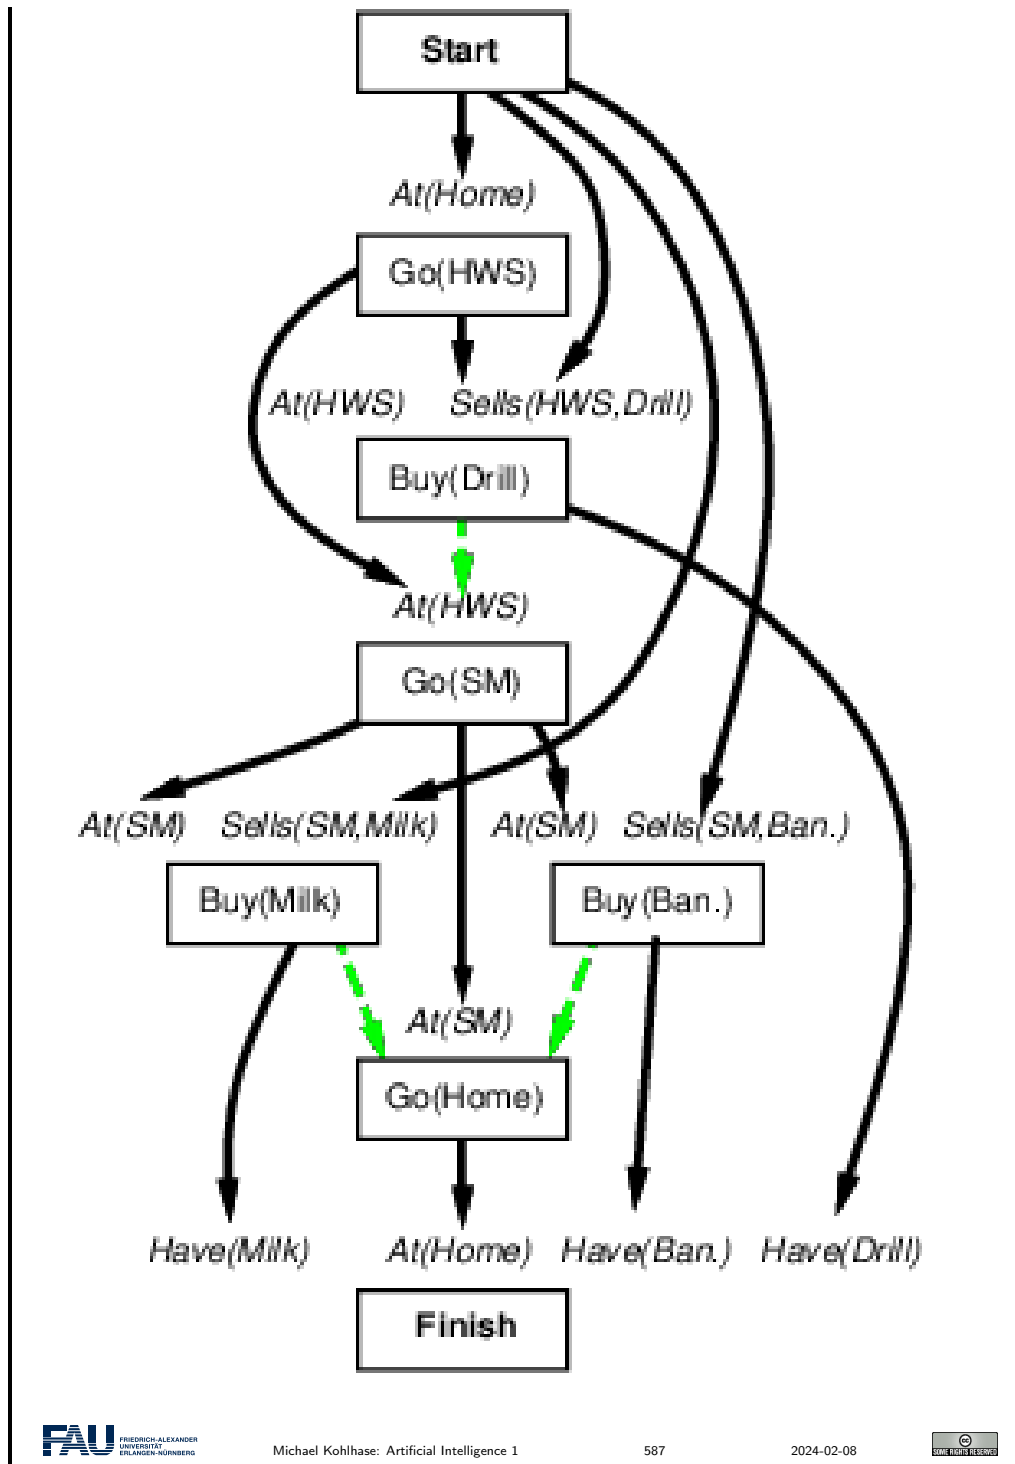

## Planning Process

- ▷ **Definition 17.5.10.** **Partial order planning** is search in the space of partial plans via the following operations:
  - ▷ **add link** from an existing action to an open precondition,
  - ▷ **add step** (an action with links to other **steps**) to fulfil an open condition,
  - ▷ **order** one **step** wrt. another to remove possible conflicts.
- ▷ **Idea:** Gradually move from incomplete/vague plans to complete, correct plans.  
**backtrack** if an open condition is unachievable or if a conflict is unresolvable.

## Example: Shopping for Bananas, Milk, and a Cordless Drill

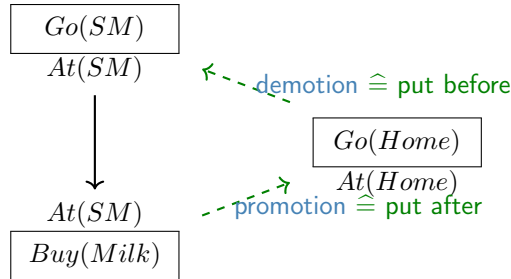

## Clobbering and Promotion/Demotion

- ▷ **Definition 17.5.11.** In a partially ordered plan, a step  $C$  **clobbers** a causal link  $L: = S \xrightarrow{p} T$ , iff it destroys the condition  $p$  achieved by  $L$ .

- ▷ **Definition 17.5.12.** If  $C$  clobbers  $S \xrightarrow{p} T$  in a partially ordered plan  $\Pi$ , then we can solve the induced conflict by
  - ▷ **demotion:** add a temporal constraint  $C \prec S$  to  $\Pi$ , or
  - ▷ **promotion:** add  $T \prec C$  to  $\Pi$ .
- ▷ **Example 17.5.13.**  $Go(Home)$  clobbers  $At(Supermarket)$ :

## POP algorithm sketch

- ▷ **Definition 17.5.14.** The POP algorithm for constructing complete partially ordered plans:

```

function POP (initial, goal, operators) : plan
 plan := Make-Minimal-Plan(initial, goal)
 loop do
 if Solution?(goal, plan) then return plan
 $S_{need}, c :=$ Select-Subgoal(plan)
 Choose-Operator(plan, operators, S_{need}, c)
 Resolve-Threats(plan)
 end

```

```

function Select-Subgoal (plan, S_{need}, c)
 pick a plan step S_{need} from Steps(plan)
 with a precondition c that has not been achieved
 return S_{need}, c

```

## POP algorithm contd.

- ▷ **Definition 17.5.15.** The missing parts for the POP algorithm.

```

function Choose-Operator (plan, operators, S_{need}, c)
 choose a step S_{add} from operators or Steps(plan) that has c as an effect
 if there is no such step then fail
 add the causal-link $S_{add} \xrightarrow{c} S_{need}$ to Links(plan)

```

```

add the temporal-constraint $S_{add} \prec S_{need}$ to Orderings(plan)
if S_{add} is a newly added \step from operators then
 add S_{add} to Steps(plan)
 add $Start \prec S_{add} \prec Finish$ to Orderings(plan)

function Resolve-Threats (plan)
 for each S_{threat} that threatens a causal-link $S_i \xrightarrow{c} S_j$ in Links(plan) do
 choose either
 demotion: Add $S_{threat} \prec S_i$ to Orderings(plan)
 promotion: Add $S_j \prec S_{threat}$ to Orderings(plan)
 if not Consistent(plan) then fail

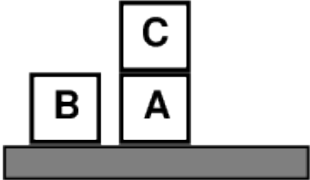

```

## Properties of POP

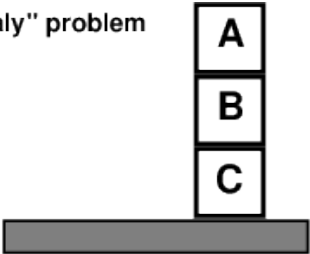

- ▷ Nondeterministic algorithm: backtracks at choice points on failure:
  - ▷ choice of  $S_{add}$  to achieve  $S_{need}$ ,
  - ▷ choice of demotion or promotion for clobberer,
  - ▷ selection of  $S_{need}$  is irrevocable.
- ▷ **Observation 17.5.16.** POP is *sound*, *complete*, and *systematic* i.e. no repetition
- ▷ There are extensions for disjunction, universals, negation, conditionals.
- ▷ It can be made efficient with good heuristics derived from problem description.
- ▷ Particularly good for problems with many loosely related subgoals.

## Example: Solving the Sussman Anomaly

**"Sussman anomaly" problem**

Start State

Goal State

$Clear(x) \ On(x,z) \ Clear(y)$

PutOn(x,y)

$\sim On(x,z) \ \sim Clear(y)$   
 $Clear(z) \ On(x,y)$

$Clear(x) \ On(x,z)$

PutOnTable(x)

$\sim On(x,z) \ Clear(z) \ On(x, Table)$

+ several inequality constraints

### Example: Solving the Sussman Anomaly (contd.)

▷ **Example 17.5.17.** Solving the Sussman anomaly

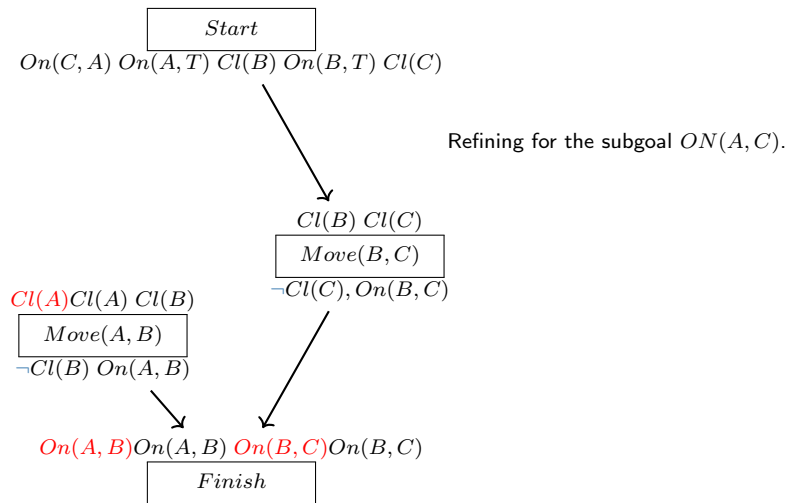

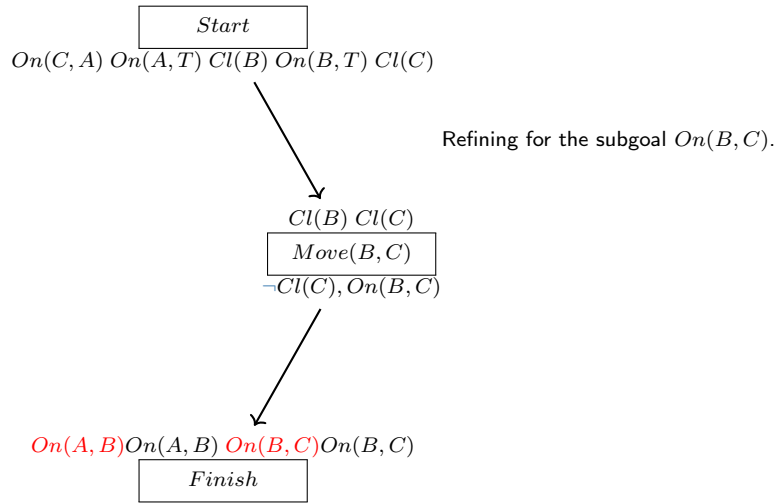

Start

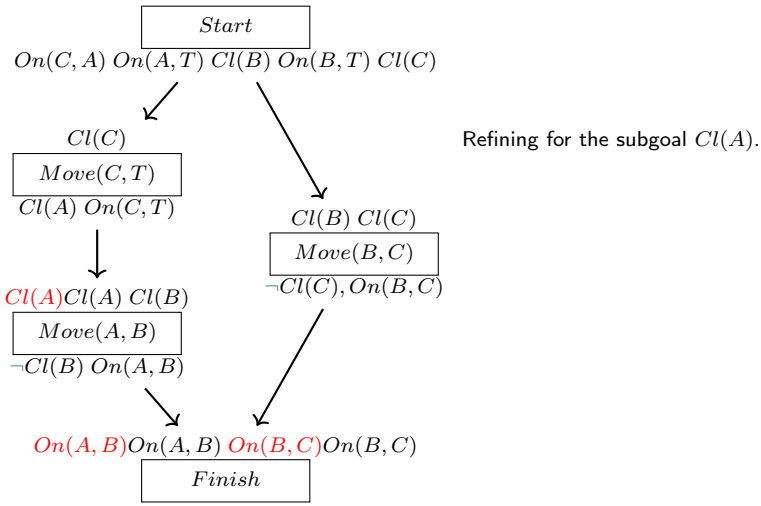

$On(C, A) \ On(A, T) \ Cl(B) \ On(B, T) \ Cl(C)$

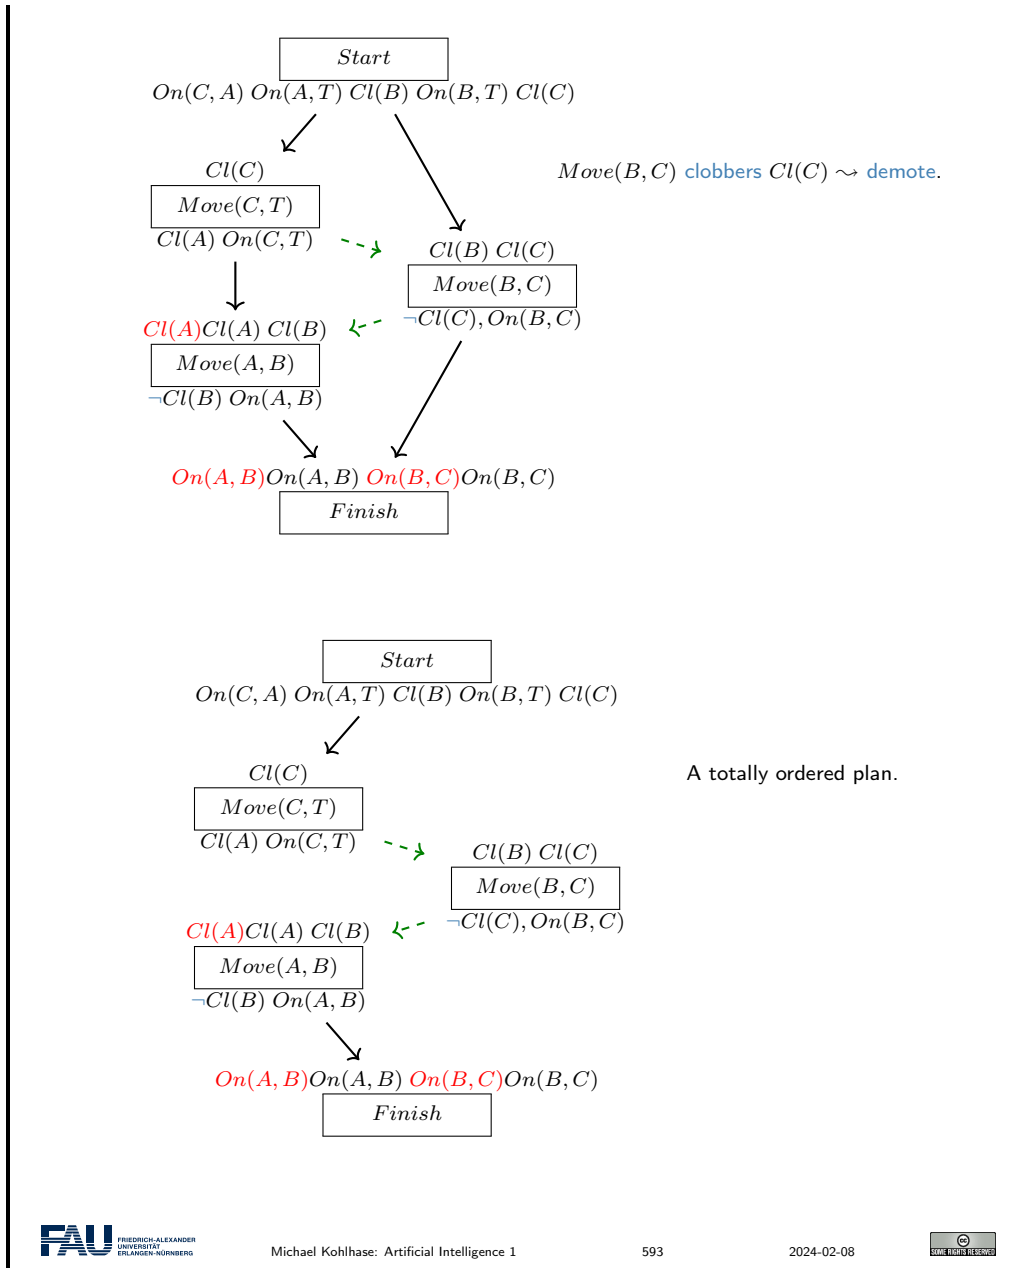

Initializing the partial order plan with with Start and Finish.

$On(A, B) \ On(A, B) \ On(B, C) \ On(B, C)$

Finish

## 17.6 The PDDL Language

A Video Nugget covering this section can be found at <https://fau.tv/clip/id/26897>.

### PDDL: Planning Domain Description Language

- ▷ **Definition 17.6.1.** The **Planning Domain Description Language (PDDL)** is a standardized representation language for planning **benchmarks** in various extensions of the **STRIPS** formalism.
- ▷ **Definition 17.6.2.** **PDDL** is not a propositional language

- ▷ Representation is lifted, using **object variables** to be instantiated from a **finite set of objects**. (Similar to predicate logic)
- ▷ **Action schemas** parameterized by **objects**.
- ▷ **Predicates** to be instantiated with **objects**.
- ▷ **Definition 17.6.3.** A **PDDL planning task** comes in two pieces
  - ▷ The **problem file** gives the objects, the initial state, and the goal state.
  - ▷ The **domain file** gives the predicates and the **actions**.

### History and Versions:

- Used in the [International Planning Competition \(IPC\)](#).
- 1998: PDDL [McD+98].
- 2000: “PDDL subset for the 2000 competition” [Bac00].
- 2002: PDDL2.1, Levels 1-3 [FL03].
- 2004: PDDL2.2 [HE05].
- 2006: PDDL3 [Ger+09].

### The Blockworld in PDDL: Domain File

```
(define (domain blockworld)
 (:predicates (clear ?x) (holding ?x) (on ?x ?y)
 (on-table ?x) (arm-empty))
 (:action stack
 :parameters (?x ?y)
 :precondition (and (clear ?y) (holding ?x))
 :effect (and (arm-empty) (on ?x ?y)
 (not (clear ?y)) (not (holding ?x))))
 ...)
```

### The Blockworld in PDDL: Problem File

```
(define (problem bw-abcde)
 (:domain blocksworld)
 (:objects a b c d e)
 (:init (on-table a) (clear a)
 (on-table b) (clear b)
 (on-table e) (clear e)
 (on-table c) (on d c) (clear d)
 (arm-empty))
 (:goal (and (on e c) (on c a) (on b d))))
```

## Miconic-ADL “Stop” Action Schema in PDDL

```
(:action stop
 :parameters (?f - floor)

```

## Planning Domain Description Language

▷ **Question:** What is PDDL good for?

- (A) Nothing.
- (B) Free beer.
- (C) Those AI planning guys.

(D) Being lazy at work.

▷ **Answer:** reserved for the plenary sessions  $\rightsquigarrow$  be there!

## 17.7 Conclusion

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/26900>.

### Summary

- ▷ General problem solving attempts to develop solvers that perform well across a large class of problems.
- ▷ Planning, as considered here, is a form of general problem solving dedicated to the class of classical search problems. (Actually, we also address inaccessible, stochastic, dynamic, continuous, and multi-agent settings.)
- ▷ **Heuristic search** planning has dominated the **International Planning Competition (IPC)**. We focus on it here.
- ▷ **STRIPS** is the simplest possible, while reasonably expressive, language for our purposes. It uses Boolean variables (facts), and defines **actions** in terms of precondition, add list, and delete list.
- ▷ PDDL is the de-facto standard language for describing planning problems.
- ▷ Plan existence (bounded or not) is **PSPACE**-complete to decide for **STRIPS**. If we bound **plans** polynomially, we get down to **NP**-completeness.

### Suggested Reading:

- Chapters 10: *Classical Planning* and 11: *Planning and Acting in the Real World* in [RN09].
  - Although the book is named “*A Modern Approach*”, the planning section was written long before the **IPC** was even dreamt of, before **PDDL** was conceived, and several years before **heuristic search** hit the scene. As such, what we have right now is the attempt of two outsiders trying in vain to catch up with the dramatic changes in planning since 1995.
  - Chapter 10 is Ok as a background read. Some issues are, imho, misrepresented, and it’s far from being an up-to-date account. But it’s Ok to get some additional intuitions in words different from my own.
  - Chapter 11 is useful in our context here because we don’t cover any of it. If you’re interested in extended/alternative planning paradigms, do read it.
- A good source for modern information (some of which we covered in the lecture) is Jörg Hoffmann’s *Everything You Always Wanted to Know About Planning (But Were Afraid to Ask)* [Hof11] which is available online at <http://fai.cs.uni-saarland.de/hoffmann/papers/ki11.pdf>

# Chapter 18

## Planning II: Algorithms

### 18.1 Introduction

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/26901>.

#### Reminder: Our Agenda for This Topic

- ▷ **chapter 17**: Background, **planning languages**, **complexity**.
  - ▷ Sets up the framework. **computational complexity** is essential to distinguish different **algorithmic** problems, and for the design of **heuristic functions**.
- ▷ **This Chapter**: How to automatically generate a **heuristic function**, given **planning language** input?
  - ▷ Focussing on **heuristic search** as the solution method, this is the main question that needs to be answered.

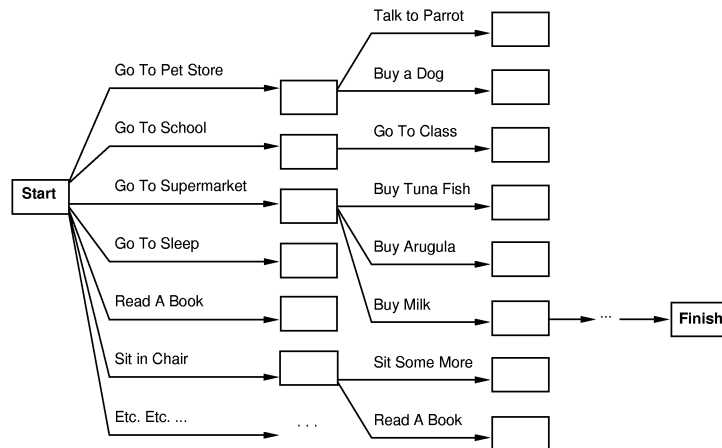

#### Reminder: Search

- ▷ Starting at **initial state**, produce all **successor states** step by step:

In **planning**, this is referred to as **forward search**, or **forward state-space search**.

## Search in the State Space?

▷ Use **heuristic function** to guide the search towards the goal!

## Reminder: Informed Search

▷ **Heuristic function**  $h$  estimates the cost of an optimal path from a **state**  $s$  to the **goal state**; search prefers to expand **states**  $s$  with small  $h(s)$ .

▷ Live Demo vs. Breadth-First Search:

<http://qiao.github.io/PathFinding.js/visual/>

### Reminder: Heuristic Functions

- ▷ **Definition 18.1.1.** Let  $\Pi$  be a STRIPS task with states  $S$ . A **heuristic function**, short **heuristic**, for  $\Pi$  is a function  $h: S \rightarrow \mathbb{N} \cup \{\infty\}$  so that  $h(s) = 0$  whenever  $s$  is a goal state.
- ▷ Exactly like our definition from chapter 6. Except, because we assume unit costs here, we use  $\mathbb{N}$  instead of  $\mathbb{R}^+$ .
- ▷ **Definition 18.1.2.** Let  $\Pi$  be a STRIPS task with states  $S$ . The **perfect heuristic**  $h^*$  assigns every  $s \in S$  the length of a shortest path from  $s$  to a goal state, or  $\infty$  if no such path exists. A heuristic function  $h$  for  $\Pi$  is **admissible** if, for all  $s \in S$ , we have  $h(s) \leq h^*(s)$ .
- ▷ Exactly like our definition from chapter 6, except for path *length* instead of path *cost* (cf. above).
- ▷ In all cases, we attempt to approximate  $h^*(s)$ , the length of an optimal plan for  $s$ . Some **algorithms** guarantee to lower bound  $h^*(s)$ .

### Our (Refined) Agenda for This Chapter

- ▷ **How to Relax:** How to relax a problem?
  - ▷ Basic principle for generating **heuristic functions**.
- ▷ **The Delete Relaxation:** How to relax a planning problem?
  - ▷ The delete relaxation is the most successful method for the *automatic* generation of **heuristic functions**. It is a key ingredient to almost all **IPC** winners of the last decade. It relaxes **STRIPS tasks** by ignoring the delete lists.
- ▷ **The  $h^+$  Heuristic:** What is the resulting **heuristic function**?
  - ▷  $h^+$  is the “ideal” delete relaxation heuristic.
- ▷ **Approximating  $h^+$ :** How to actually compute a **heuristic**?
  - ▷ Turns out that, in practice, we must approximate  $h^+$ .

## 18.2 How to Relax in Planning

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/26902>.

We will now instantiate our general knowledge about **heuristic search** to the planning domain. As always, the main problem is to find good **heuristics**. We will follow the intuitions of our discussion in subsection 6.5.4 and consider full solutions to **relaxed problems** as a source for **heuristics**.

### How to Relax

- ▷ **Recall:** We introduced the concept of a **relaxed search problem** (allow cheating) to derive **heuristics** from them.
- ▷ **Observation:** This can be generalized to arbitrary **problem solving**.
- ▷ **Definition 18.2.1 (The General Case).**

1. You have a class  $\mathcal{P}$  of problems, whose **perfect heuristic**  $h_{\mathcal{P}}^*$  you wish to estimate.
2. You define a class  $\mathcal{P}'$  of *simpler problems*, whose **perfect heuristic**  $h_{\mathcal{P}'}^*$  can be used to estimate  $h_{\mathcal{P}}^*$ .
3. You define a transformation – the **relaxation mapping**  $\mathcal{R}$  – that maps instances  $\Pi \in \mathcal{P}$  into instances  $\Pi' \in \mathcal{P}'$ .
4. Given  $\Pi \in \mathcal{P}$ , you let  $\Pi' := \mathcal{R}(\Pi)$ , and estimate  $h_{\mathcal{P}}^*(\Pi)$  by  $h_{\mathcal{P}'}^*(\Pi')$ .

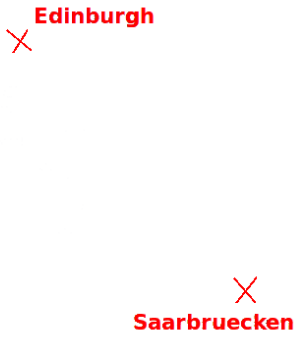

- ▷ **Definition 18.2.2.** For **planning tasks**, we speak of **relaxed planning**.

## Reminder: Heuristic Functions from Relaxed Problems

## How to Relax in Planning? (A Reminder!)

- ▷ **Example 18.2.3 (Logistics).**

  - ▷ facts  $P$ :  $\{\text{truck}(x) \mid x \in \{A, B, C, D\}\} \cup \{\text{pack}(x) \mid x \in \{A, B, C, D, T\}\}$ .
  - ▷ initial state  $I$ :  $\{\text{truck}(A), \text{pack}(C)\}$ .
  - ▷ goal state  $G$ :  $\{\text{truck}(A), \text{pack}(D)\}$ .
  - ▷ actions  $A$ : (Notated as “precondition  $\Rightarrow$  adds,  $\neg$  deletes”)
    - ▷  $\text{drive}(x, y)$ , where  $x$  and  $y$  have a road: “ $\text{truck}(x) \Rightarrow \text{truck}(y), \neg \text{truck}(x)$ ”.
    - ▷  $\text{load}(x)$ : “ $\text{truck}(x), \text{pack}(x) \Rightarrow \text{pack}(T), \neg \text{pack}(x)$ ”.
    - ▷  $\text{unload}(x)$ : “ $\text{truck}(x), \text{pack}(T) \Rightarrow \text{pack}(x), \neg \text{pack}(T)$ ”.
- ▷ **Example 18.2.4 (“Only-Adds” Relaxation).** Drop the preconditions and deletes.
  - ▷ “ $\text{drive}(x, y) \Rightarrow \text{truck}(y)$ ”;
  - ▷ “ $\text{load}(x) \Rightarrow \text{pack}(T)$ ”;
  - ▷ “ $\text{unload}(x) \Rightarrow \text{pack}(x)$ ”.
- ▷ Heuristics value for  $I$  is?
- ▷  $h^{\mathcal{R}}(I) = 1$ : A plan for the relaxed task is  $\langle \text{unload}(D) \rangle$ .

Michael Kohlhase: Artificial Intelligence 1
611
2024-02-08

We will start with a very simple **relaxation**, which could be termed “positive thinking”: we do not

consider preconditions of actions and leave out the delete lists as well.

### How to Relax During Search: Overview

---

▷ **Attention:** Search uses the real (un-relaxed)  $\Pi$ . The relaxation is applied (e.g., in Only-Adds, the simplified actions are used) **only within the call to  $h(s)$ !!!**

▷ Here,  $\Pi_s$  is  $\Pi$  with initial state replaced by  $s$ , i.e.,  $\Pi := \langle P, A, I, G \rangle$  changed to  $\Pi^s := \langle P, A, \{s\}, G \rangle$ : The task of finding a plan for search state  $s$ .

▷ A common student mistake is to instead apply the relaxation once to the whole problem, then doing the whole search “within the relaxation”.

▷ The next slide illustrates the correct search process in detail.

### Only-Adds is a "Native" Relaxation

▷ **Definition 18.2.5 (Native Relaxations).** Confusing special case where  $\mathcal{P}' \subseteq \mathcal{P}$ .

The diagram shows a box labeled  $\mathcal{P}$  on the left and a box labeled  $\mathbb{N} \cup \{\infty\}$  on the right. Inside the  $\mathcal{P}$  box, there is a smaller box labeled  $\mathcal{P}' \subseteq \mathcal{P}$ . An arrow labeled  $\mathcal{R}$  points from the  $\mathcal{P}$  box to the  $\mathcal{P}' \subseteq \mathcal{P}$  box. Two arrows point from the boxes to the right box: one from the main  $\mathcal{P}$  box labeled  $h_{\mathcal{P}}^*$ , and one from the  $\mathcal{P}' \subseteq \mathcal{P}$  box labeled  $h_{\mathcal{P}'}^*$ .

- ▷ **Problem class  $\mathcal{P}$ :** STRIPS tasks.
- ▷ **Perfect heuristic  $h_{\mathcal{P}}^*$  for  $\mathcal{P}$ :** Length  $h^*$  of a shortest plan.
- ▷ **Transformation  $\mathcal{R}$ :** Drop the preconditions and delete lists.
- ▷ **Simpler problem class  $\mathcal{P}'$**  is a special case of  $\mathcal{P}$ ,  $\mathcal{P}' \subseteq \mathcal{P}$ : STRIPS tasks with empty preconditions and delete lists.
- ▷ Perfect heuristic for  $\mathcal{P}'$ : Shortest plan for only-adds STRIPS task.

## 18.3 The Delete Relaxation

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/26903>. We turn to a more realistic *relaxation*, where we only disregard the delete list.

### How the Delete Relaxation Changes the World (I)

▷ Relaxation mapping  $\mathcal{R}$  saying that:

**“When the world changes, its previous state remains true as well.”**

Real world: (before)

Real world: (after)

world: (before)

Relaxed world: (after)

## How the Delete Relaxation Changes the World (II)

▷ Relaxation mapping  $\mathcal{R}$  saying that:

Real world: (before)

Real world: (after)

Relaxed world: (before)

Relaxed world: (after)

## How the Delete Relaxation Changes the World (III)

▷ Relaxation mapping  $\mathcal{R}$  saying that:

## The Delete Relaxation

▷ **Definition 18.3.1 (Delete Relaxation).** Let  $\Pi := \langle P, A, I, G \rangle$  be a STRIPS task. The **delete relaxation** of  $\Pi$  is the task  $\Pi^+ = \langle P, A^+, I, G \rangle$  where  $A^+ := \{a^+ \mid a \in A\}$  with  $\text{pre}_{a^+} := \text{pre}_a$ ,  $\text{add}_{a^+} := \text{add}_a$ , and  $\text{del}_{a^+} := \emptyset$ .

- ▷ In other words, the class of simpler problems  $\mathcal{P}'$  is the set of all STRIPS tasks with empty delete lists, and the relaxation mapping  $\mathcal{R}$  drops the delete lists.
- ▷ **Definition 18.3.2 (Relaxed Plan).** Let  $\Pi := \langle P, A, I, G \rangle$  be a STRIPS task, and let  $s$  be a state. A relaxed plan for  $s$  is a plan for  $\langle P, A, s, G \rangle^+$ . A relaxed plan for  $I$  is called a relaxed plan for  $\Pi$ .
- ▷ A relaxed plan for  $s$  is an action sequence that solves  $s$  when pretending that all delete lists are empty.
- ▷ Also called **delete-relaxed plan**: “relaxation” is often used to mean delete relaxation by default.

## A Relaxed Plan for “TSP” in Australia

1. **Initial state:**  $\{\text{at}(\text{Sy}), \text{vis}(\text{Sy})\}$ .
2.  $\text{drv}(\text{Sy}, \text{Br})^+ : \{\text{at}(\text{Br}), \text{vis}(\text{Br}), \text{at}(\text{Sy}), \text{vis}(\text{Sy})\}$ .
3.  $\text{drv}(\text{Sy}, \text{Ad})^+ : \{\text{at}(\text{Ad}), \text{vis}(\text{Ad}), \text{at}(\text{Br}), \text{vis}(\text{Br}), \text{at}(\text{Sy}), \text{vis}(\text{Sy})\}$ .
4.  $\text{drv}(\text{Ad}, \text{Pe})^+ : \{\text{at}(\text{Pe}), \text{vis}(\text{Pe}), \text{at}(\text{Ad}), \text{vis}(\text{Ad}), \text{at}(\text{Br}), \text{vis}(\text{Br}), \text{at}(\text{Sy}), \text{vis}(\text{Sy})\}$ .
5.  $\text{drv}(\text{Ad}, \text{Da})^+ : \{\text{at}(\text{Da}), \text{vis}(\text{Da}), \text{at}(\text{Pe}), \text{vis}(\text{Pe}), \text{at}(\text{Ad}), \text{vis}(\text{Ad}), \text{at}(\text{Br}), \text{vis}(\text{Br}), \text{at}(\text{Sy}), \text{vis}(\text{Sy})\}$ .

## A Relaxed Plan for “Logistics”

- ▷ **Facts  $P$ :**  $\{\text{truck}(x) | x \in \{A, B, C, D\}\} \cup \{\text{pack}(x) | x \in \{A, B, C, D, T\}\}$ .
- ▷ **Initial state  $I$ :**  $\{\text{truck}(A), \text{pack}(C)\}$ .
- ▷ **Goal  $G$ :**  $\{\text{truck}(D), \text{pack}(D)\}$ .
- ▷ **Relaxed actions  $A^+$ :** (Notated as “precondition  $\Rightarrow$  adds”)
  - ▷  $\text{drive}(x, y)^+ : \text{“truck}(x) \Rightarrow \text{truck}(y)”$ .

- ▷  $\text{load}(x)^+$ : “ $\text{truck}(x), \text{pack}(x) \Rightarrow \text{pack}(T)$ ”.
- ▷  $\text{unload}(x)^+$ : “ $\text{truck}(x), \text{pack}(T) \Rightarrow \text{pack}(x)$ ”.

**Relaxed plan:**

$\langle \text{drive}(A, B)^+, \text{drive}(B, C)^+, \text{load}(C)^+, \text{drive}(C, D)^+, \text{unload}(D)^+ \rangle$

- ▷ We don't need to drive the truck back, because “it is still at  $A$ ”.

## PlanEx<sup>+</sup>

- ▷ **Definition 18.3.3 (Relaxed Plan Existence Problem).** By **PlanEx<sup>+</sup>**, we denote the problem of deciding, given a STRIPS task  $\Pi := \langle P, A, I, G \rangle$ , whether or not there exists a relaxed plan for  $\Pi$ .

- ▷ This is easier than **PlanEx** for general STRIPS!

- ▷ **PlanEx<sup>+</sup>** is in **P**.

- ▷ *Proof:* The following algorithm decides **PlanEx<sup>+</sup>**

1.

```

var $F := I$
while $G \not\subseteq F$ do
 $F' := F \cup \bigcup_{a \in A: \text{pre}_a \subseteq F} \text{add}_a$
 if $F' = F$ then return “unsolvable” endif (*)
 $F := F'$
endwhile
return “solvable”

```

2. The algorithm terminates after at most  $|P|$  iterations, and thus runs in polynomial time.
3. **Correctness:** See slide 624

## Deciding PlanEx<sup>+</sup> in “TSP” in Australia

Iterations on  $F$ :

1.  $\{at(Sy), vis(Sy)\}$
2.  $\cup \{at(Ad), vis(Ad), at(Br), vis(Br)\}$
3.  $\cup \{at(Da), vis(Da), at(Pe), vis(Pe)\}$

## Deciding PlanEx<sup>+</sup> in “Logistics”

### ▷ Example 18.3.4 (The solvable Case).

#### Iterations on $F$ :

1.  $\{truck(A), pack(C)\}$
2.  $\cup \{truck(B)\}$
3.  $\cup \{truck(C)\}$
4.  $\cup \{truck(D), pack(T)\}$
5.  $\cup \{pack(A), pack(B), pack(D)\}$

### ▷ Example 18.3.5 (The unsolvable Case).

#### Iterations on $F$ :

1.  $\{truck(A), pack(C)\}$
2.  $\cup \{truck(B)\}$
3.  $\cup \{truck(C)\}$
4.  $\cup \{pack(T)\}$
5.  $\cup \{pack(A), pack(B)\}$
6.  $\cup \emptyset$

## PlanEx<sup>+</sup> Algorithm: Proof

*Proof:* To show: The algorithm returns “solvable” iff there is a relaxed plan for II.

1. Denote by  $F_i$  the content of  $F$  after the  $i$ th iteration of the while-loop,
2. All  $a \in A_0$  are applicable in  $I$ , all  $a \in A_1$  are applicable in  $\text{apply}(I, A_0^+)$ , and so forth.
3. Thus  $F_i = \text{apply}(I, \langle A_0^+, \dots, A_{i-1}^+ \rangle)$ . (Within each  $A_j^+$ , we can sequence the actions in any order.)
4. Direction “ $\Rightarrow$ ” If “solvable” is returned after iteration  $n$  then  $G \subseteq F_n = \text{apply}(I, \langle A_0^+, \dots, A_{n-1}^+ \rangle)$  so  $\langle A_0^+, \dots, A_{n-1}^+ \rangle$  can be sequenced to a relaxed plan which shows the claim.
5. Direction “ $\Leftarrow$ ”
  - 5.1. Let  $\langle a_0^+, \dots, a_{n-1}^+ \rangle$  be a relaxed plan, hence  $G \subseteq \text{apply}(I, \langle a_0^+, \dots, a_{n-1}^+ \rangle)$ .
  - 5.2. Assume, for the moment, that we drop line (\*) from the algorithm. It is then

easy to see that  $a_i \in A_i$  and  $\text{apply}(I, \langle a_0^+, \dots, a_{i-1}^+ \rangle) \subseteq F_i$ , for all  $i$ .

5.3. We get  $G \subseteq \text{apply}(I, \langle a_0^+, \dots, a_{n-1}^+ \rangle) \subseteq F_n$ , and the algorithm returns “solvable” as desired.

5.4. Assume to the contrary of the claim that, in an iteration  $i < n$ , (\*) fires. Then  $G \not\subseteq F$  and  $F = F'$ . But, with  $F = F'$ ,  $F = F_j$  for all  $j > i$ , and we get  $G \not\subseteq F_n$  in contradiction.

## 18.4 The $h^+$ Heuristic

A Video Nugget covering this section can be found at <https://fau.tv/clip/id/26905>.

### Hold on a Sec – Where are we?

- ▷  $\mathcal{P}$ : STRIPS tasks;  $h^*_{\mathcal{P}}$ : Length  $h^*$  of a shortest plan.
- ▷  $\mathcal{P}' \subseteq \mathcal{P}$ : STRIPS tasks with empty delete lists.
- ▷  $\mathcal{R}$ : Drop the delete lists.
- ▷ Heuristic function: Length of a shortest relaxed plan ( $h^* \circ \mathcal{R}$ ).
- ▷  $\text{PlanEx}^+$  is not actually what we're looking for.  $\text{PlanEx}^+ \hat{=}$  relaxed plan existence; we want relaxed plan length  $h^* \circ \mathcal{R}$ .

### $h^+$ : The Ideal Delete Relaxation Heuristic

- ▷ **Definition 18.4.1 (Optimal Relaxed Plan).** Let  $\langle P, A, I, G \rangle$  be a STRIPS task, and let  $s$  be a state. A **optimal relaxed plan** for  $s$  is an optimal plan for  $\langle P, A, \{s\}, G \rangle^+$ .
- ▷ Same as slide 618, just adding the word “optimal”.
- ▷ Here's what we're looking for:
- ▷ **Definition 18.4.2.** Let  $\Pi := \langle P, A, I, G \rangle$  be a STRIPS task with states  $S$ . The **ideal delete relaxation heuristic**  $h^+$  for  $\Pi$  is the function  $h^+ : S \rightarrow \mathbb{N} \cup \{\infty\}$  where  $h^+(s)$  is the length of an optimal relaxed plan for  $s$  if a relaxed plan for  $s$  exists, and  $h^+(s) = \infty$  otherwise.
- ▷ In other words,  $h^+ = h^* \circ \mathcal{R}$ , cf. previous slide.

## $h^+$ is Admissible

▷ **Lemma 18.4.3.** Let  $\Pi := \langle P, A, I, G \rangle$  be a STRIPS task, and let  $s$  be a state. If  $\langle a_1, \dots, a_n \rangle$  is a plan for  $\Pi_s := \langle P, A, \{s\}, G \rangle$ , then  $\langle a_1^+, \dots, a_n^+ \rangle$  is a plan for  $\Pi^+$ .

▷ *Proof sketch:* Show by induction over  $0 \leq i \leq n$  that  $\text{apply}(s, \langle a_1, \dots, a_i \rangle) \subseteq \text{apply}(s, \langle a_1^+, \dots, a_i^+ \rangle)$ .

▷ If we ignore deletes, the states along the plan can only get bigger.

▷ **Theorem 18.4.4.**  $h^+$  is Admissible.

▷ *Proof:*

1. Let  $\Pi := \langle P, A, I, G \rangle$  be a STRIPS task with states  $P$ , and let  $s \in P$ .
2.  $h^+(s)$  is defined as optimal plan length in  $\Pi_s^+$ .
3. With the lemma above, any plan for  $\Pi$  also constitutes a plan for  $\Pi_s^+$ .
4. Thus optimal plan length in  $\Pi_s^+$  can only be shorter than that in  $\Pi_s$ , and the claim follows.

## How to Relax During Search: Ignoring Deletes

### Real problem:

▷ Initial state  $I$ :  $AC$ ; goal  $G$ :  $AD$ .

▷ Actions  $A$ : pre, add, del.

▷  $drXY, loX, ulX$ .

Greedy best-first search:

(tie-breaking: alphabetic)

We are here

### Relaxed problem:

▷ State  $s$ :  $AC$ ; goal  $G$ :  $AD$ .

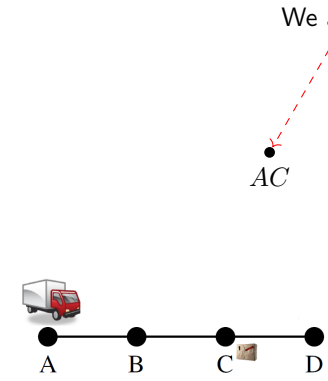

▷ Actions  $A$ : pre, add.

▷  $h^+(s) = 5$ : e.g.  $\langle drAB, drBC, drCD, loC, ulD \rangle$ .

Greedy best-first search:

(tie-breaking: alphabetic)

We are here

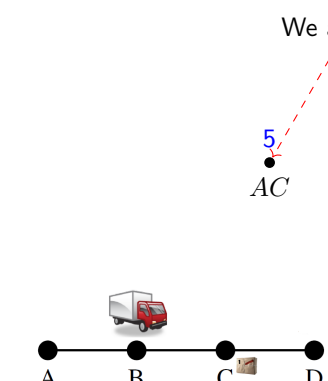

**Relaxed problem:**

- ▷ State  $s$ :  $AC$ ; goal  $G$ :  $AD$ .
- ▷ Actions  $A$ : pre, add.
- ▷  $h^+(s) = 5$ : e.g.  $\langle drAB, drBC, drCD, loC, ulD \rangle$ .  
(tie-breaking: alphabetic)

**Greedy best-first search:**

We are here

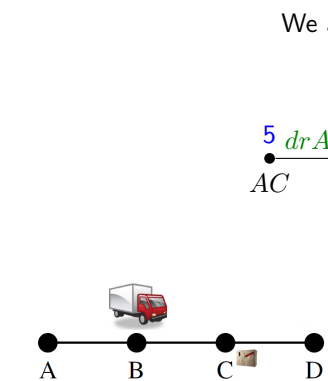

**Real problem:**

- ▷ State  $s$ :  $BC$ ; goal  $G$ :  $AD$ .

**Greedy best-first search:**

(tie-breaking: alphabetic)

**Real problem:**

▷ State  $s$ :  $CD$ ; goal  $G$ :  $AD$ .

▷ Actions  $A$ :  $pre, add, del$ .

▷ Successors:  $BD, DD$ .

**Greedy best-first search:**

(tie-breaking: alphabetic)

**Real problem:**

▷ State  $s$ :  $BD$ ; goal  $G$ :  $AD$ .

▷ Actions  $A$ :  $pre, add, del$ .

▷ Successors:  $AD, CD$ .

**Greedy best-first search:**

(tie-breaking: alphabetic)

**Real problem:**

- ▷ State  $s$ : AD; goal  $G$ : AD.
- ▷ Actions  $A$ : pre, add, del.
- ▷ Goal state!

**Greedy best-first search:** (tie-breaking: alphabetic)

Of course there are also bad cases. Here is one.

### $h^+$ in the Blockworld

- ▷ **Optimal plan:**  $\langle \text{putdown}(A), \text{unstack}(B, D), \text{stack}(B, C), \text{pickup}(A), \text{stack}(A, B) \rangle$ .
- ▷ **Optimal relaxed plan:**  $\langle \text{stack}(A, B), \text{unstack}(B, D), \text{stack}(B, C) \rangle$ .
- ▷ **Observation:** What can we say about the “search space surface” at the initial state here?

- ▷ The **initial state** lies on a **local minimum** under  $h^+$ , together with the **successor state**  $s$  where we stacked  $A$  onto  $B$ . All direct other neighbors of these two **states** have a strictly higher  $h^+$  value.

## 18.5 Conclusion

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/26906>.

### Summary

- ▷ **Heuristic search** on classical **search problems** relies on a **function**  $h$  mapping **states**  $s$  to an estimate  $h(s)$  of their **goal state** distance. Such **functions**  $h$  are derived by solving **relaxed problems**.
- ▷ In **planning**, the **relaxed** problems are generated and solved automatically. There are four known families of suitable relaxation methods: *abstractions*, *landmarks*, *critical paths*, and *ignoring deletes* (aka **delete relaxation**).
- ▷ The **delete relaxation** consists in dropping the **deletes** from **STRIPS tasks**. A **relaxed plan** is a **plan** for such a **relaxed task**.  $h^+(s)$  is the length of an optimal relaxed plan for **state**  $s$ .  $h^+$  is **NP-hard** to compute.
- ▷  $h^{FF}$  approximates  $h^+$  by computing some, not necessarily optimal, relaxed plan. That is done by a forward pass (building a *relaxed planning graph*), followed by a backward pass (*extracting a relaxed plan*).

### Topics We Didn't Cover Here

- ▷ **Abstractions, Landmarks, Critical-Path Heuristics, Cost Partitions, Compatibility between Heuristic Functions, Planning Competitions:**
- ▷ **Tractable fragments:** Planning sub-classes that can be solved in polynomial time. Often identified by properties of the “causal graph” and “domain transition graphs”.
- ▷ **Planning as SAT:** Compile length- $k$  bounded plan existence into satisfiability of a CNF formula  $\varphi$ . Extensive literature on how to obtain small  $\varphi$ , how to schedule different values of  $k$ , how to modify the underlying SAT solver.
- ▷ **Compilations:** Formal framework for determining whether planning formalism  $X$  is (or is not) at least as expressive as planning formalism  $Y$ .
- ▷ **Admissible pruning/decomposition methods:** Partial-order reduction, symmetry reduction, simulation-based dominance **pruning**, **factored planning**, decoupled search.
- ▷ **Hand-tailored planning:** Automatic planning is the extreme case where the **computer** is given no domain knowledge other than “physics”. We can instead allow the

user to provide search control knowledge, trading off modeling effort against search performance.

▷ **Numeric planning, temporal planning, planning under uncertainty . . .**

### Suggested Reading (RN: Same As Previous Chapter):

- Chapters 10: *Classical Planning* and 11: *Planning and Acting in the Real World* in [RN09].
  - Although the book is named “*A Modern Approach*”, the planning section was written long before the IPC was even dreamt of, before PDDL was conceived, and several years before heuristic search hit the scene. As such, what we have right now is the attempt of two outsiders trying in vain to catch up with the dramatic changes in planning since 1995.
  - Chapter 10 is Ok as a background read. Some issues are, imho, misrepresented, and it’s far from being an up-to-date account. But it’s Ok to get some additional intuitions in words different from my own.
  - Chapter 11 is useful in our context here because we don’t cover any of it. If you’re interested in extended/alternative planning paradigms, do read it.
- A good source for modern information (some of which we covered in the lecture) is Jörg Hoffmann’s *Everything You Always Wanted to Know About Planning (But Were Afraid to Ask)* [Hof11] which is available online at <http://fai.cs.uni-saarland.de/hoffmann/papers/ki11.pdf>

# Chapter 19

## Searching, Planning, and Acting in the Real World

### Outline

- ▷ **So Far:** we made idealizing/simplifying assumptions:  
The environment is fully observable and deterministic.
- ▷ **Outline:** In this chapter we will lift some of them
  - ▷ The real world (things go wrong)
  - ▷ Agents and Belief States
  - ▷ Conditional planning
  - ▷ Monitoring and replanning
- ▷ **Note:** The considerations in this chapter apply to both search and planning.

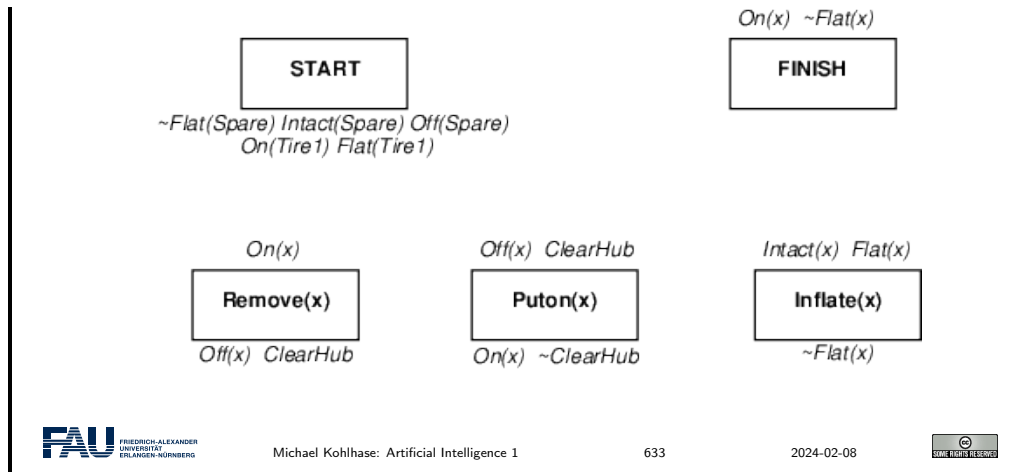

### 19.1 Introduction

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/26908>.

#### The real world

- ▷ **Example 19.1.1.** We have a flat tire – what to do?

## Generally: Things go wrong (in the real world)

- ▷ **Example 19.1.2 (Incomplete Information).**
  - ▷ Unknown **preconditions**, e.g.,  $Intact(Spare)$ ?
  - ▷ Disjunctive **effects**, e.g.,  $Inflate(x)$  causes  $Inflated(x) \vee SlowHiss(x) \vee Burst(x) \vee BrokenPump \vee \dots$
- ▷ **Example 19.1.3 (Incorrect Information).**
  - ▷ Current **state** incorrect, e.g., spare NOT intact
  - ▷ Missing/incorrect **effects** in **actions**.
- ▷ **Definition 19.1.4.** The **qualification problem** in planning is that we can never finish listing all the required **preconditions** and possible conditional **effects** of **actions**.
- ▷ **Root Cause:** The **environment** is **partially observable** and/or **non-deterministic**.
- ▷ **Technical Problem:** We cannot know the “current state of the world”, but search/-planning **algorithms** are based on this assumption.
- ▷ **Idea:** Adapt search/planning **algorithms** to work with “sets of possible states”.

## What can we do if things (can) go wrong?

- ▷ **One Solution:** **Sensorless planning:** **plans** that work regardless of state/outcome.
- ▷ **Problem:** Such **plans** may not exist! (but they often do in practice)
- ▷ **Another Solution:** **Conditional plans:**
  - ▷ Plan to obtain information, (observation actions)
  - ▷ Subplan for each contingency.

- ▷ **Example 19.1.5 (A conditional Plan).** (AAA  $\hat{=}$  ADAC)  
`[Check(T1), if Intact(T1) then Inflate(T1) else CallAAA fi]`
- ▷ **Problem:** Expensive because it **plans** for many unlikely cases.
- ▷ **Still another Solution:** Execution monitoring/replanning
  - ▷ Assume normal states/outcomes, check progress *during execution*, replan if necessary.
- ▷ **Problem:** Unanticipated outcomes may lead to failure. (e.g., no AAA card)
- ▷ **Observation 19.1.6.** *We really need a combination; plan for likely/serious eventualities, deal with others when they arise, as they must eventually.*

## 19.2 The Furniture Coloring Example

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/29180>. We now introduce a planning example that shows off the various features.

### The Furniture-Coloring Example: Specification

- ▷ **Example 19.2.1 (Coloring Furniture).**
- Paint a chair and a table in matching colors.
  - ▷ The initial state is:
    - ▷ we have two cans of paint of unknown color,
    - ▷ the color of the furniture is unknown as well,
    - ▷ only the table is in the agent's field of view.
  - ▷ **Actions:**
    - ▷ remove lid from can
    - ▷ paint object with paint from open can.

We formalize the example in PDDL for simplicity. Note that the `:percept` scheme is not part of the official PDDL, but fits in well with the design.

### The Furniture-Coloring Example: PDDL

- ▷ **Example 19.2.2 (Formalization in PDDL).**
- ▷ The **PDDL domain file** is as expected (actions below)
 

```
(define (domain furniture-coloring)
 (:predicates (object ?x) (can ?x) (inview ?x) (color ?x ?y))
 ...)
```

- ▷ The PDDL problem file has a “free” variable ?c for the (undetermined) joint color.

```
(define (problem tc-coloring)
 (:domain furniture-objects)
 (:objects table chair c1 c2)
 (:init (object table) (object chair) (can c1) (can c2) (inview table))
 (:goal (color chair ?c) (color table ?c)))
```

- ▷ Two action schemata: *remove can lid to open* and *paint with open can*

```
(:action remove-lid
 :parameters (?x)
 :precondition (can ?x)
 :effect (open can))
(:action paint
 :parameters (?x ?y)
 :precondition (and (object ?x) (can ?y) (color ?y ?c) (open ?y))
 :effect (color ?x ?c))
```

has a universal variable ?c for the paint action ⇐ we cannot just give paint a color argument in a partially observable environment.

- ▷ **Sensorless Plan:** Open one can, paint chair and table in its color.
- ▷ **Note:** Contingent planning can create better plans, but needs perception
- ▷ Two percept schemata: *color of an object* and *color in a can*

```
(:percept color
 :parameters (?x ?c)
 :precondition (and (object ?x) (inview ?x)))
(:percept can-color
 :parameters (?x ?c)
 :precondition (and (can ?x) (inview ?x) (open ?x)))
```

To perceive the color of an object, it must be in view, a can must also be open.

**Note:** In a fully observable world, the percepts would not have preconditions.

- ▷ An action schema: *look at an object* that causes it to come into view.

```
(:action lookat
 :parameters (?x)
 :precond: (and (inview ?y) and (notequal ?x ?y))
 :effect (and (inview ?x) (not (inview ?y))))
```

- ▷ **Contingent Plan:**

1. look at furniture to determine color, if same ⇨ done.
2. else, look at open and look at paint in cans
3. if paint in one can is the same as an object, paint the other with this color
4. else paint both in any color

## 19.3 Searching/Planning with Non-Deterministic Actions

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/29181>.

### Conditional Plans

- ▷ **Definition 19.3.1.** Conditional plans extend the possible actions in plans by conditional steps that execute sub plans conditionally whether  $K + P \models C$ , where  $K + P$  is the current knowledge base + the percepts.
- ▷ **Definition 19.3.2.** Conditional plans can contain
  - ▷ conditional step:  $[\dots, \text{if } C \text{ then } Plan_A \text{ else } Plan_B \text{ fi}, \dots]$ ,
  - ▷ while step:  $[\dots, \text{while } C \text{ do } Plan \text{ done}, \dots]$ , and
  - ▷ the empty plan  $\emptyset$  to make modeling easier.
- ▷ **Definition 19.3.3.** If the possible percepts are limited to determining the current state in a conditional plan, then we speak of a contingency plan.
- ▷ **Note:** Need some plan for every possible percept! Compare to
  - game playing:** some response for every opponent move.
  - backchaining:** some rule such that every premise satisfied.
- ▷ **Idea:** Use an AND-OR tree search (very similar to backward chaining algorithm)

### Contingency Planning: The Erratic Vacuum Cleaner

- ▷ **Example 19.3.4 (Erratic vacuum world).**

A variant suck action:  
if square is

- ▷ dirty: clean the square, sometimes remove dirt in adjacent square.
- ▷ clean: sometimes deposits dirt on the carpet.

Solution:  $[suck, \text{if } State = 5 \text{ then } [right, suck] \text{ else } [] \text{ fi}]$

### Conditional AND-OR Search (Data Structure)

- ▷ **Idea:** Use **AND-OR trees** as **data structures** for representing problems (or goals) that can be reduced to conjunctions and disjunctions of subproblems (or sub-goals).
- ▷ **Definition 19.3.5.** An **AND-OR graph** is a **graph** whose **non-terminal nodes** are partitioned into **AND nodes** and **OR nodes**. A **valuation** of an **AND-OR graph**  $T$  is an assignment of **T** or **F** to the nodes of  $T$ . A **valuation** of the **terminal nodes** of  $T$  can be extended by all **nodes** recursively: Assign **T** to an
  - ▷ **OR node**, iff at least one of its **children** is **T**.
  - ▷ **AND node**, iff all of its **children** are **T**.
- A **solution** for  $T$  is a **valuation** that assigns **T** to the **initial nodes** of  $T$ .
- ▷ **Idea:** A **planning task** with non deterministic **actions** generates a **AND-OR graph**  $T$ . A **solution** that assigns **T** to a **terminal node**, iff it is a goal node. Corresponds to a **conditional plan**.

## Conditional AND-OR Search (Example)

- ▷ **Definition 19.3.6.** An **AND-OR tree** is a **AND-OR graph** that is also a **tree**.
- Notation:** **AND nodes** are written with arcs connecting the **child edges**.
- ▷ **Example 19.3.7 (An AND-OR-tree).**

## Conditional AND-OR Search (Algorithm)

- ▷ **Definition 19.3.8.** **AND-OR search** is an **algorithm** for searching **AND-OR graphs** generated by nondeterministic environments.
- function** **AND/OR-GRAPH-SEARCH**(*prob*) **returns** a conditional plan, or **fail**
- OR-SEARCH**(*prob*.INITIAL-STATE, *prob*, [])
- function** **OR-SEARCH**(*state*, *prob*, *path*) **returns** a conditional plan, or **fail**

```

if prob.GOAL-TEST(state) then return the empty plan
if state is on path then return fail
for each action in prob.ACTIONS(state) do
 plan := AND-SEARCH(RESULTS(state,action),prob,[state | path])
 if plan ≠ fail then return [action | plan]
return fail
function AND-SEARCH(states,prob,path) returns a conditional plan, or fail
for each s_i in states do
 $p_i :=$ OR-SEARCH(s_i ,prob,path)
if $p_i =$ fail then return fail
return [if s_1 then p_1 else if s_2 then p_2 else ... if s_{n-1} then p_{n-1} else p_n]

```

- ▷ **Cycle Handling:** If a state has been seen before  $\rightsquigarrow$  **fail**
  - ▷ **fail** does not mean *there is no solution*, but
  - ▷ *if there is a non-cyclic solution, then it is reachable by an earlier incarnation!*

## The Slippery Vacuum Cleaner (try, try, try, ... try again)

- ▷ **Example 19.3.9 (Slippery Vacuum World).**

Moving sometimes fails  
 $\rightsquigarrow$  AND-OR graph

Two possible solutions (depending on what our plan language allows)

- ▷  $[L_1 : \textit{left}, \textit{if } AtR \textit{ then } L_1 \textit{ else } [\textit{if } CleanL \textit{ then } \emptyset \textit{ else suck fi}] \textit{ fi}]$  or
- ▷  $[\textit{while } AtR \textit{ do } [\textit{left}] \textit{ done}, \textit{if } CleanL \textit{ then } \emptyset \textit{ else suck fi}]$
- ▷ We have an **infinite loop** but **plan** eventually works unless action always fails.

## AI-1 Survey on ALeA

- ▷ Online survey evaluating ALeA from 7.02.24 to 29.02.24 24:00 (Feb last)
- ▷ Works on all common devices (mobile phone, notebook, etc.)

- ▷ Is in english Takes about 10 - 20 min depending on proficiency in english and using ALeA
- ▷ Questions about how ALeA is used, what it is like using ALeA, and questions about demography
- ▷ Token generated at the end of the survey (SAVE THIS CODE!)
  - ▷ Completed survey count as a successful tuesday quiz in AI1!
  - ▷ Look for Quiz 15 in the usual place (single question)
  - ▷ just submit the token to get full points
  - ▷ The token can also be used to exercise the rights of the GDPR.
- ▷ Survey has no timelimit and is free, anonymous, can be paused and continued later on and can be cancelled.

## Find the Survey Here

<https://ddi-survey.cs.fau.de/limesurvey/ALeA>

This URL will also be posted on the forum tonight.

## 19.4 Agent Architectures based on Belief States

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/29182>.

We are now ready to proceed to **environments** which can only **partially observed** and where our actions are **non deterministic**. Both sources of **uncertainty** conspire to allow us only partial knowledge about the world, so that we can only optimize “**expected utility**” instead of “**actual utility**” of our actions.

### World Models for Uncertainty

- ▷ **Problem:** We do not know with certainty what state the world is in!
- ▷ **Idea:** Just keep track of all the possible **states** it could be in.
- ▷ **Definition 19.4.1.** A **model-based agent** has a **world model** consisting of
  - ▷ a **belief state** that has information about the possible **states** the world may be in, and
  - ▷ a **sensor model** that updates the **belief state** based on **sensor** information
  - ▷ a **transition model** that updates the **belief state** based on **actions**.
- ▷ **Idea:** The **agent environment** determines what the **world model** can be.
- ▷ In a **fully observable, deterministic environment**,
  - ▷ we can observe the initial **state** and subsequent **states** are given by the **actions** alone.
  - ▷ thus the **belief state** is a **singleton** (we call its member the **world state**) and the **transition model** is a function from **states** and **actions** to **states**: a **transition function**.

That is exactly what we have been doing until now: we have been studying methods that build on descriptions of the “actual” world, and have been concentrating on the progression from **atomic** to **factored** and ultimately **structured** representations. Tellingly, we spoke of “world states” instead of “belief states”; we have now justified this practice in the brave new belief-based world models by the (re-) definition of “world states” above. To fortify our intuitions, let us recap from a belief-state-model perspective.

## World Models by Agent Type in AI-1

- ▷ **Note:** All of these considerations only give requirements to the world model. What we can do with it depends on representation and inference.
- ▷ **Search-based Agents:** In a **fully observable, deterministic environment**
  - ▷ **goal-based agent** with **world state**  $\hat{=}$  “current state”
  - ▷ no inference. (**goal**  $\hat{=}$  **goal state from search problem**)
- ▷ **CSP-based Agents:** In a **fully observable, deterministic environment**
  - ▷ **goal-based agent** with **world state**  $\hat{=}$  constraint network,
  - ▷ inference  $\hat{=}$  constraint propagation. (**goal**  $\hat{=}$  **satisfying assignment**)
- ▷ **Logic-based Agents:** In a **fully observable, deterministic environment**
  - ▷ **model-based agent** with **world state**  $\hat{=}$  logical formula
  - ▷ inference  $\hat{=}$  e.g. DPLL or resolution. (**no decision theory covered in AI-1**)
- ▷ **Planning Agents:** In a **fully observable, deterministic, environment**
  - ▷ **goal-based agent** with **world state**  $\hat{=}$  PL0, **transition model**  $\hat{=}$  STRIPS,
  - ▷ inference  $\hat{=}$  state/plan space search. (**goal**: **complete plan/execution**)

Let us now see what happens when we lift the restrictions of **total observability** and **determinism**.

## World Models for Complex Environments

- ▷ In a **fully observable**, but **stochastic environment**,
  - ▷ the **belief state** must deal with a set of possible **states**.
  - ▷  $\rightsquigarrow$  generalize the **transition function** to a **transition relation**.
- ▷ **Note:** This even applies to **online problem solving**, where we can just perceive the state. (e.g. **when we want to optimize utility**)
- ▷ In a **deterministic**, but **partially observable environment**,
  - ▷ the **belief state** must deal with a set of possible **states**.
  - ▷ we can use **transition functions**.
  - ▷ We need a **sensor model**, which predicts the influence of **percepts** on the **belief state** – during update.
- ▷ In a **stochastic, partially observable environment**,
  - ▷ mix the ideas from the last two. (sensor model + transition relation)

## Preview: New World Models (Belief) $\rightsquigarrow$ new Agent Types

- ▷ **Probabilistic Agents:** In a **partially observable environment**
  - ▷ belief state  $\hat{=}$  Bayesian networks,
  - ▷ inference  $\hat{=}$  probabilistic inference.
- ▷ **Decision-Theoretic Agents:**
  - In a **partially observable, stochastic environment**
    - ▷ belief state + transition model  $\hat{=}$  decision networks,
    - ▷ inference  $\hat{=}$  maximizing expected utility.
  - ▷ We will study them in detail in the coming semester.

## 19.5 Searching/Planning without Observations

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/29183>.

### Conformant/Sensorless Planning

- ▷ **Definition 19.5.1.** **Conformant** or **sensorless planning** tries to find **plans** that work without any sensing. (not even the initial state)

- ▷ **Example 19.5.2 (Sensorless Vacuum Cleaner World).**

States	integer dirt and robot locations
Actions	<i>left, right, suck, noOp</i>
Goal states	<i>notdirty?</i>

- ▷ **Observation 19.5.3.** In a sensorless world we do not know the initial state. (or any state after)
- ▷ **Observation 19.5.4.** *Sensorless planning* must search in the space of *belief states* (sets of possible actual states).
- ▷ **Example 19.5.5 (Searching the Belief State Space).**

- ▷ Start in  $\{1, 2, 3, 4, 5, 6, 7, 8\}$
- ▷ **Solution:**  $[right, suck, left, suck]$
- |              |                              |
|--------------|------------------------------|
| <i>right</i> | $\rightarrow \{2, 4, 6, 8\}$ |
| <i>suck</i>  | $\rightarrow \{4, 8\}$       |
| <i>left</i>  | $\rightarrow \{3, 7\}$       |
| <i>suck</i>  | $\rightarrow \{7\}$          |

## Search in the Belief State Space: Let's Do the Math

- ▷ **Recap:** We describe an **search problem**  $\Pi := \langle \mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$  via its **states**  $\mathcal{S}$ , **actions**  $\mathcal{A}$ , and **transition model**  $\mathcal{T}: \mathcal{A} \times \mathcal{S} \rightarrow \mathcal{P}(\mathcal{A})$ , **goal states**  $\mathcal{G}$ , and **initial state**  $\mathcal{I}$ .
- ▷ **Problem:** What is the corresponding sensorless problem?
- ▷ **Let' think:** Let  $\Pi := \langle \mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$  be a (physical) problem
- ▷ **States**  $\mathcal{S}^b$ : The **belief states** are the  $2^{|\mathcal{S}|}$  subsets of  $\mathcal{S}$ .
  - ▷ The **initial state**  $\mathcal{I}^b$  is just  $\mathcal{S}$  (no information)
  - ▷ **Goal states**  $\mathcal{G}^b := \{S \in \mathcal{S}^b \mid S \subseteq \mathcal{G}\}$  (all possible states must be physical goal states)
  - ▷ **Actions**  $\mathcal{A}^b$ : we just take  $\mathcal{A}$ . (that's the point!)
  - ▷ **Transition model**  $\mathcal{T}^b: \mathcal{A}^b \times \mathcal{S}^b \rightarrow \mathcal{P}(\mathcal{A}^b)$ : i.e. what is  $\mathcal{T}^b(a, S)$  for  $a \in \mathcal{A}$  and  $S \subseteq \mathcal{S}$ ? This is slightly tricky as  $a$  need not be **applicable** to all  $s \in S$ .
    1. if **actions** are harmless to the environment, take  $\mathcal{T}^b(a, S) := \bigcup_{s \in S} \mathcal{T}(a, s)$ .
    2. if not, better take  $\mathcal{T}^b(a, S) := \bigcap_{s \in S} \mathcal{T}(a, s)$ . (the safe bet)
- ▷ **Observation 19.5.6.** In belief-state space the problem is always fully observable!

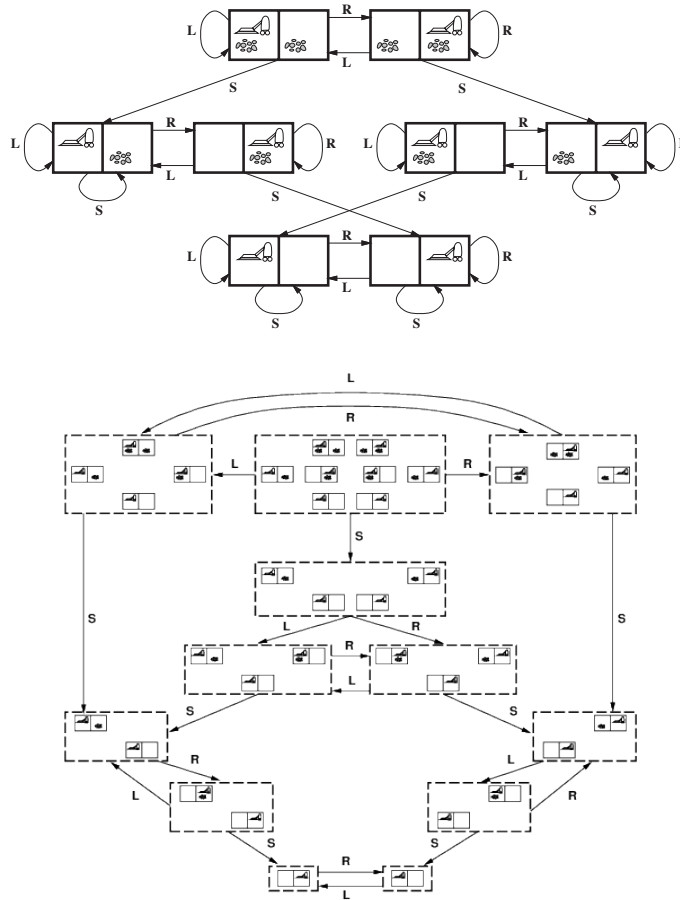

Let us see if we can understand the options for  $\mathcal{T}^b(a, S)$  a bit better. The first question is when we want an action  $a$  to be applicable to a **belief state**  $S \subseteq \mathcal{S}$ , i.e. when should  $\mathcal{T}^b(a, S)$  be non-empty.

In the first case,  $a^b$  would be applicable iff  $a$  is applicable to some  $s \in S$ , in the second case if  $a$  is applicable to all  $s \in S$ . So we only want to choose the first case if actions are harmless.

The second question we ask ourselves is what should be the results of applying  $a$  to  $S \subseteq \mathcal{S}$ ?, again, if actions are harmless, we can just collect the results, otherwise, we need to make sure that all members of the result  $a^b$  are reached for all possible states in  $S$ .

## State Space vs. Belief State Space

- ▷ **Example 19.5.7 (State/Belief State Space in the Vacuum World).** In the vacuum world all actions are always applicable (1./2. equal)

## Evaluating Conformant Planning

- ▷ **Upshot:** We can build belief-space problem formulations automatically,  
 ▷ but they are exponentially bigger in theory, in practice they are often similar;  
 ▷ e.g. 12 reachable belief states out of  $2^8 = 256$  for vacuum example.
- ▷ **Problem:** Belief states are HUGE; e.g. initial belief state for the  $10 \times 10$  vacuum

world contains  $100 \cdot 2^{100} \approx 10^{32}$  physical states

- ▷ **Idea:** Use planning techniques: compact descriptions for
  - ▷ belief states; e.g. *all* for initial state or *not leftmost column* after *left*.
  - ▷ actions as belief state to belief state operations.
- ▷ **This actually works:** Therefore we talk about conformant planning!

## 19.6 Searching/Planning with Observation

A Video Nugget covering this section can be found at <https://fau.tv/clip/id/29184>.

### Conditional planning (Motivation)

- ▷ **Note:** So far, we have never used the agent's sensors.
  - ▷ In chapter 6, since the environment was observable and deterministic we could just use offline planning.
  - ▷ In section 19.5 because we chose to.
- ▷ **Note:** If the world is nondeterministic or partially observable then percepts usually provide information, i.e., split up the belief state

- ▷ **Idea:** This can systematically be used in search/planning via belief-state search, but we need to rethink/specialize the Transition model.

### A Transition Model for Belief-State Search

- ▷ We extend the ideas from slide 651 to include partial observability.
- ▷ **Definition 19.6.1.** Given a (physical) search problem  $\Pi := \langle \mathcal{S}, \mathcal{A}, \mathcal{T}, \mathcal{I}, \mathcal{G} \rangle$ , we define the belief state search problem induced by  $\Pi$  to be  $\langle \mathcal{P}(\mathcal{S}), \mathcal{A}, \mathcal{T}^b, \mathcal{S}, \{S \in \mathcal{S}^b \mid S \subseteq \mathcal{G}\} \rangle$ , where the transition model  $\mathcal{T}^b$  is constructed in three stages:
  - ▷ The prediction stage: given a belief state  $b$  and an action  $a$  we define  $\hat{b} := \text{PRED}(b, a)$  for some function  $\text{PRED}: \mathcal{P}(\mathcal{S}) \times \mathcal{A} \rightarrow \mathcal{P}(\mathcal{S})$ .
  - ▷ The observation prediction stage determines the set of possible percepts that could be observed in the predicted belief state:  $\text{PossPERC}(\hat{b}) = \{\text{PERC}(s) \mid s \in \hat{b}\}$ .

- ▷ The **update** stage determines, for each possible percept, the resulting belief state:  $\text{UPDATE}(\hat{b}, o) := \{s \mid o = \text{PERC}(s) \text{ and } s \in \hat{b}\}$

The functions **PRED** and **PERC** are the main parameters of this model. We define  $\text{RESULT}(b, a) := \{\text{UPDATE}(\text{PRED}(b, a), o) \mid \text{PossPERC}(\text{PRED}(b, a))\}$

- ▷ **Observation 19.6.2.** We always have  $\text{UPDATE}(\hat{b}, o) \subseteq \hat{b}$ .
- ▷ **Observation 19.6.3.** If sensing is deterministic, belief states for different possible percepts are disjoint, forming a partition of the original predicted belief state.

## Example: Local Sensing Vacuum Worlds

- ▷ **Example 19.6.4 (Transitions in the Vacuum World).** Deterministic World:

The action *Right* is deterministic, sensing **disambiguates** to **singletons** Slippery World:

The action *Right* is non-deterministic, sensing **disambiguates** somewhat

### Belief-State Search with Percepts

- ▷ **Observation:** The belief-state transition model induces an AND-OR graph.
- ▷ **Idea:** Use AND-OR search in non deterministic environments.
- ▷ **Example 19.6.5.** AND-OR graph for initial percept  $[A, Dirty]$ .

**Solution:**  $[Suck, Right, \text{if } Bstate = \{6\} \text{ then } Suck \text{ else } [] \text{ fi}]$

- ▷ **Note:** Belief-state-problem  $\rightsquigarrow$  conditional step tests on belief-state percept (plan would not be executable in a partially observable environment otherwise)

### Example: Agent Localization

- ▷ **Example 19.6.6.** An agent inhabits a maze of which it has an accurate map. It has four sensors that can (reliably) detect walls. The *Move* action is non-deterministic, moving the agent randomly into one of the adjacent squares.

1. Initial belief state  $\rightsquigarrow \hat{b}_1$  all possible locations.
2. Initial percept:  $NWS$  (walls north, west, and south)  $\rightsquigarrow \hat{b}_2 = \text{UPDATE}(\hat{b}_1, NWS)$

3. Agent executes *Move*  $\rightsquigarrow \hat{b}_3 = \text{PRED}(\hat{b}_2, \text{Move}) = \text{one step away from these.}$
4. Next percept:  $NS$   $\rightsquigarrow \hat{b}_4 = \text{UPDATE}(\hat{b}_3, NS)$

All in all,  $\hat{b}_4 = \text{UPDATE}(\text{PRED}(\text{UPDATE}(\hat{b}_1, \text{NWS}), \text{Move}), \text{NS})$  localizes the agent.

- ▷ **Observation:** **PRED** enlarges the belief state, while **UPDATE** shrinks it again.

## Contingent Planning

- ▷ **Definition 19.6.7.** The generation of plan with conditional branching based on percepts is called **contingent planning**, solutions are called **contingent plans**.

- ▷ Appropriate for partially observable or non-deterministic environments.

- ▷ **Example 19.6.8.** Continuing Example 19.2.1.

One of the possible **contingent plan** is

((lookat table) (lookat chair)

  (if (and (color table c) (color chair c)) (noop)

    (removeid c1) (lookat c1) (removeid c2) (lookat c2)

    (if (and (color table c) (color can c)) ((paint chair can))

      (if (and (color chair c) (color can c)) ((paint table can))

        ((paint chair c1) (paint table c1))))))

- ▷ **Note:** Variables in this plan are existential; e.g. in

- ▷ line 2: If there is some joint color  $c$  of the table and chair  $\leadsto$  done.

- ▷ line 4/5: Condition can be satisfied by  $[c_1/can]$  or  $[c_2/can] \leadsto$  instantiate accordingly.

- ▷ **Definition 19.6.9.** During **plan execution** the agent maintains the **belief state**  $b$ , chooses the branch depending on whether  $b \models c$  for the condition  $c$ .

- ▷ **Note:** The planner must make sure  $b \models c$  can always be decided.

## Contingent Planning: Calculating the Belief State

- ▷ **Problem:** How do we compute the **belief state**?

- ▷ **Recall:** Given a belief state  $b$ , the new belief state  $\hat{b}$  is computed based on prediction with the action  $a$  and the refinement with the percept  $p$ .

- ▷ **Here:**

Given an action  $a$  and percepts  $p = p_1 \wedge \dots \wedge p_n$ , we have

- ▷  $\hat{b} = b \setminus \text{del}_a \cup \text{add}_a$  (as for the sensorless agent)
- ▷ If  $n = 1$  and  $(:\text{percept } p_1 : \text{precondition } c)$  is the only percept axiom, also add  $p$  and  $c$  to  $\hat{b}$ . (add  $c$  as otherwise  $p$  impossible)
- ▷ If  $n > 1$  and  $(:\text{percept } p_i : \text{precondition } c_i)$  are the percept axioms, also add  $p$  and  $c_1 \vee \dots \vee c_n$  to  $\hat{b}$ . (belief state no longer conjunction of literals ☺)
- ▷ **Idea:** Given such a mechanism for generating (exact or approximate) updated belief states, we can generate contingent plans with an extension of AND-OR search over belief states.
- ▷ **Extension:** This also works for non-deterministic actions: we extend the representation of effects to disjunctions.

## 19.7 Online Search

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/29185>.

### Online Search and Replanning

- ▷ **Note:** So far we have concentrated on offline problem solving, where the agent only acts (plan execution) after search/planning terminates.
- ▷ **Recall:** In online problem solving an agent interleaves computation and action: it computes one action at a time based on incoming perceptions.
- ▷ Online problem solving is helpful in
  - ▷ dynamic or semidynamic environments. (long computation times can be harmful)
  - ▷ stochastic environments. (solve contingencies only when they arise)
- ▷ Online problem solving is necessary in unknown environments  $\rightsquigarrow$  exploration problem.

### Online Search Problems

- ▷ **Observation:** Online problem solving even makes sense in deterministic, fully observable environments.
- ▷ **Definition 19.7.1.** A **online search problem** consists of a set  $S$  of states, and
  - ▷ a function  $\text{Actions}(s)$  that returns a list of actions allowed in state  $s$ .
  - ▷ the step cost function  $c$ , where  $c(s, a, s')$  is the cost of executing action  $a$  in state  $s$  with outcome  $s'$ . (cost unknown before executing  $a$ )
  - ▷ a goal test **Goal Test**.
- ▷ **Note:** We can only determine  $\text{RESULT}(s, a)$  by being in  $s$  and executing  $a$ .

- ▷ **Definition 19.7.2.** The **competitive ratio** of an **online problem solving agent** is the quotient of
  - ▷ **offline performance**, i.e. cost of optimal solutions with full information and
  - ▷ **online performance**, i.e. the actual cost induced by **online problem solving**.

## Online Search Problems (Example)

- ▷ **Example 19.7.3 (A simple maze problem).**

The agent starts at  $S$  and must reach  $G$  but knows nothing of the environment. In particular not that

- ▷ Up(1,1) results in (1,2) and
- ▷ Down(1,1) results in (1,1) (i.e. back)

## Online Search Obstacles (Dead Ends)

- ▷ **Definition 19.7.4.** We call a state a **dead end**, iff no state is reachable from it by an action. An action that leads to a **dead end** is called **irreversible**.
- ▷ **Note:** With **irreversible actions** the **competitive ratio** can be **infinite**.
- ▷ **Observation 19.7.5.** No **online algorithm** can avoid **dead ends** in all **state spaces**.
- ▷ **Example 19.7.6.** Two state spaces that lead an online agent into **dead ends**:

Any agent will fail in at least one of the spaces.

- ▷ **Definition 19.7.7.** We call Example 19.7.6 an **adversary argument**.
- ▷ **Example 19.7.8.** Forcing an online agent into an arbitrarily inefficient route:

```

else $a :=$ an action b such that $result[s', b] = pop(unbacktracked[s'])$
else $a := pop(untried[s'])$
 $s := s'$
return a

```

▷ **Note:** *result* is the “environment map” constructed as the agent explores.

## 19.8 Replanning and Execution Monitoring

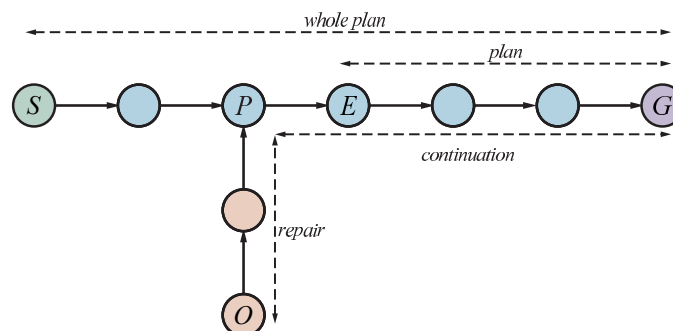

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/29186>.

### Replanning (Ideas)

- ▷ **Idea:** We can turn a planner  $P$  into an **online problem solver** by adding an action  $RePlan(g)$  without preconditions that re-starts  $P$  in the current state with goal  $g$ .
- ▷ **Observation:** Replanning induces a tradeoff between pre-planning and re-planning.
- ▷ **Example 19.8.1.** The plan  $[RePlan(g)]$  is a (trivially) complete plan for any goal  $g$ . (not helpful)
- ▷ **Example 19.8.2.** A plan with sub-plans for every contingency (e.g. what to do if a meteor strikes) may be too costly/large. (wasted effort)
- ▷ **Example 19.8.3.** But when a tire blows while driving into the desert, we want to have water pre-planned. (due diligence against catastrophies)
- ▷ **Observation:** In **stochastic** or **partially observable environments** we also need some form of execution monitoring to determine the need for replanning (plan repair).

### Replanning for Plan Repair

- ▷ **Generally:** Replanning when the agent's model of the world is incorrect.
- ▷ **Example 19.8.4 (Plan Repair by Replanning).** Given a plan from  $S$  to  $G$ .

- ▷ The agent executes *wholeplan* **step** by **step**, monitoring the rest (*plan*).
- ▷ After a few **steps** the agent expects to be in *E*, but observes state *O*.
- ▷ **Replanning**: by calling the planner recursively
  - ▷ find state *P* in *wholeplan* and a plan *repair* from *O* to *P*. (*P* may be *G*)
  - ▷ **minimize** the cost of *repair* + *continuation*

## Factors in World Model Failure $\leadsto$ Monitoring

- ▷ **Generally**: The agent's world model can be incorrect, because
  - ▷ an action has a missing precondition (need a screwdriver for remove—lid)
  - ▷ an action misses an effect (painting a table gets paint on the floor)
  - ▷ it is missing a state variable (amount of paint in a can: no paint  $\leadsto$  no color)
  - ▷ no provisions for exogenous events (someone knocks over a paint can)
- ▷ **Observation**: Without a way for monitoring for these, planning is very brittle.
- ▷ **Definition 19.8.5**. There are three levels of **execution monitoring**: before executing an action
  - ▷ **action monitoring** checks whether all preconditions still hold.
  - ▷ **plan monitoring** checks that the remaining plan will still succeed.
  - ▷ **goal monitoring** checks whether there is a better set of goals it could try to achieve.
- ▷ **Note**: Example 19.8.4 was a case of **action monitoring** leading to replanning.

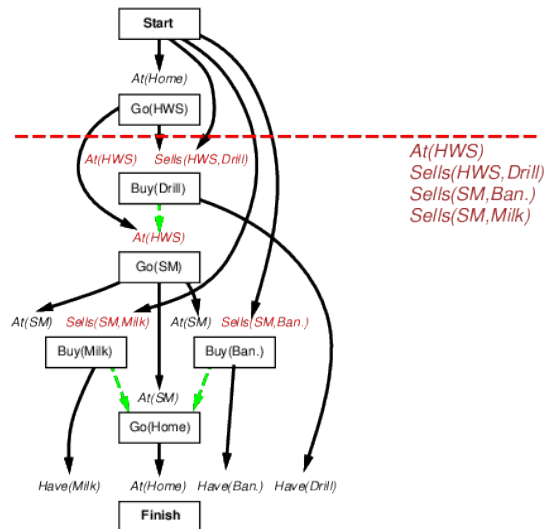

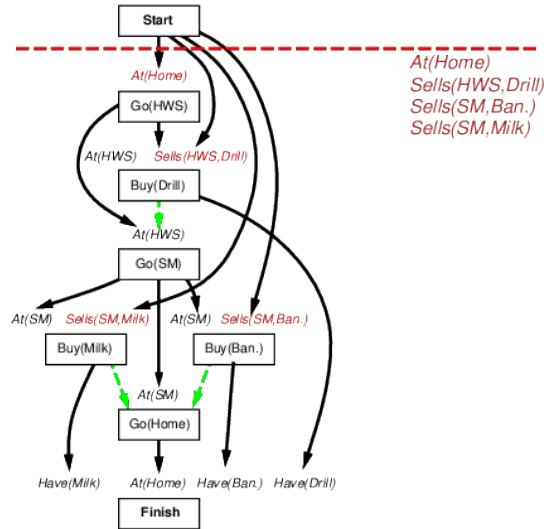

## Integrated Execution Monitoring and Planning

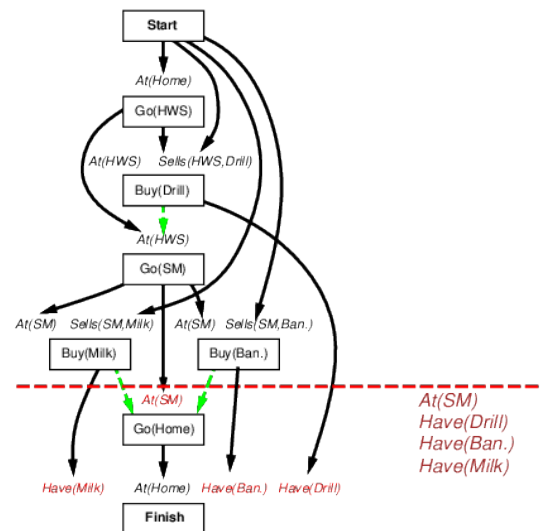

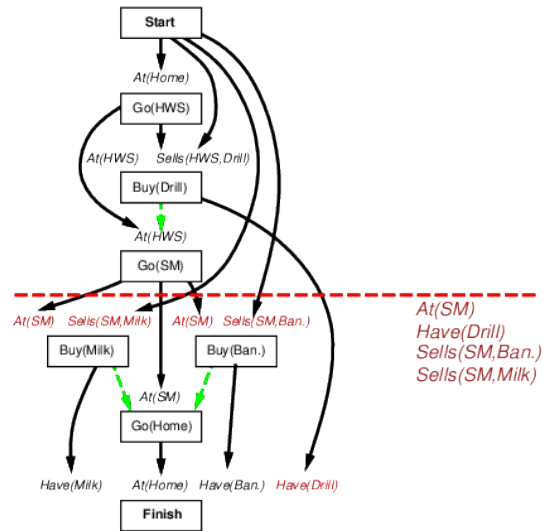

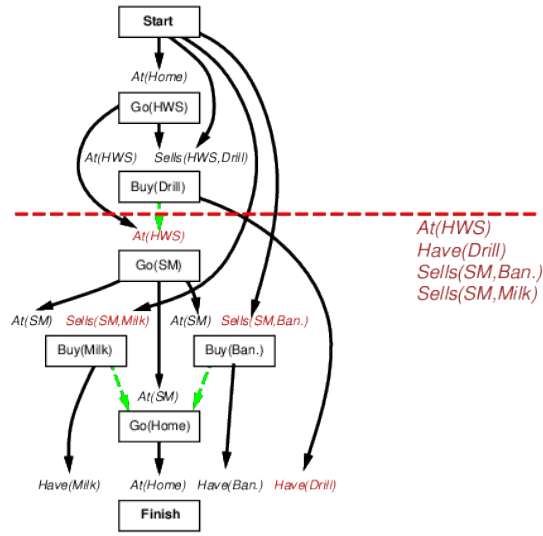

- ▷ **Problem**: Need to upgrade planing data structures by bookkeeping for **execution monitoring**.
- ▷ **Observation**: With their **causal links**, **partially ordered plans** already have most of the infrastructure for **action monitoring**:
  - Preconditions of remaining **plan**
  - $\hat{=}$  all preconditions of remaining **steps** not **achieved** by remaining **steps**
  - $\hat{=}$  all **causal link** "crossing current time point"
- ▷ **Idea**: On failure, resume planning (e.g. by **POP**) to **achieve** open conditions from current state.
- ▷ **Definition 19.8.6. IPEM (Integrated Planning, Execution, and Monitoring)**:
  - ▷ keep updating *Start* to match current state
  - ▷ links from **actions** replaced by links from *Start* when done

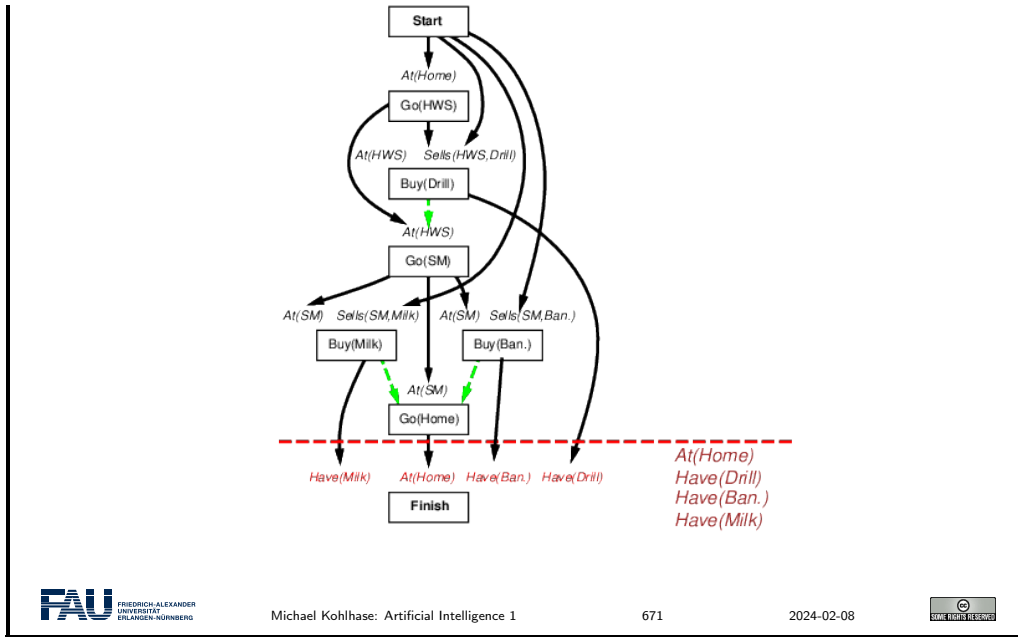

## Execution Monitoring Example

- ▷ **Example 19.8.7 (Shopping for a drill, milk, and bananas).** Start/end at home, drill sold by hardware store, milk/bananas by supermarket.

## Part V

What did we learn in AI 1?

A **Video Nugget** covering this part can be found at <https://fau.tv/clip/id/26916>.

## Topics of AI-1 (Winter Semester)

- ▷ Getting Started
  - ▷ What is **Artificial Intelligence**? (situating ourselves)
  - ▷ **Logic programming** in Prolog (An influential paradigm)
  - ▷ Intelligent Agents (a unifying framework)
- ▷ Problem Solving
  - ▷ Problem Solving and **search** (Black Box World States and Actions)
  - ▷ **Adversarial search** (Game playing) (A nice application of search)
  - ▷ **constraint satisfaction problems** (Factored World States)
- ▷ Knowledge and Reasoning
  - ▷ Formal Logic as the **mathematics** of Meaning
  - ▷ **Propositional logic** and **satisfiability** (Atomic Propositions)
  - ▷ **First-order logic** and **theorem proving** (Quantification)
  - ▷ **Logic programming** (Logic + Search  $\rightsquigarrow$  Programming)
  - ▷ **Description logics** and **semantic web**
- ▷ Planning
  - ▷ Planning Frameworks
  - ▷ Planning Algorithms
  - ▷ Planning and Acting in the real world

## Rational Agents as an Evaluation Framework for AI

- ▷ Agents interact with the environment

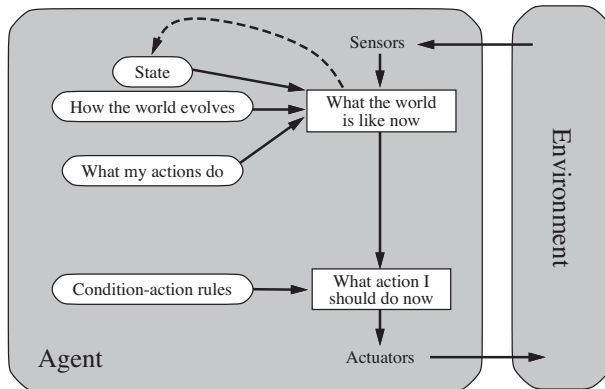

General agent schema

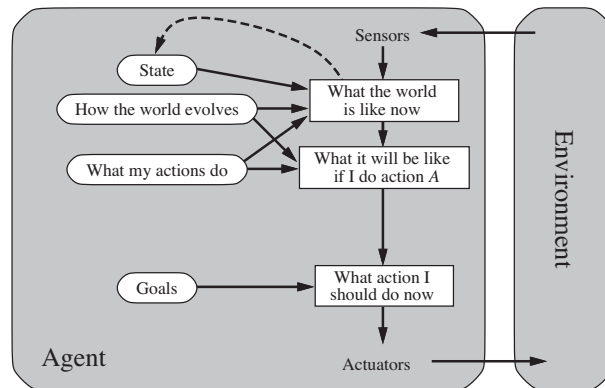

Simple Reflex Agents

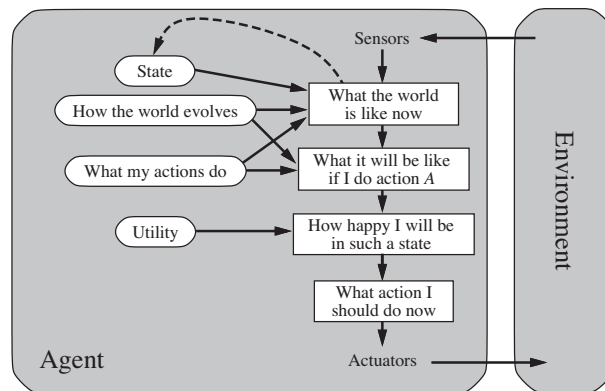

Reflex Agents with State

Goal-Based Agents

Utility-Based Agent

Learning Agents

Rational Agent

▷ Idea: Try to design agents that are successful

(do the right thing)

- ▷ **Definition 19.8.8.** An **agent** is called **rational**, if it chooses whichever **action maximizes** the expected value of the performance measure given the **percept** sequence to date. This is called the **MEU principle**.
- ▷ **Note:** A **rational agent** need not be perfect
  - ▷ only needs to **maximize expected value** (**rational  $\neq$  omniscient**)
    - ▷ need not predict e.g. very unlikely but catastrophic events in the future
  - ▷ **percepts** may not supply all relevant information (**Rational  $\neq$  clairvoyant**)
    - ▷ if we cannot perceive things we do not need to react to them.
    - ▷ but we may need to try to find out about hidden dangers (**exploration**)
  - ▷ **action** outcomes may not be as expected (**rational  $\neq$  successful**)
    - ▷ but we may need to take **action** to ensure that they do (more often) (**learning**)
- ▷ **Rational**  $\leadsto$  exploration, learning, autonomy

## Symbolic AI: Adding Knowledge to Algorithms

- ▷ Problem Solving (**Black Box States, Transitions, Heuristics**)
  - ▷ **Framework:** Problem Solving and Search (**basic tree/graph walking**)
  - ▷ **Variants:** Game playing (**Adversarial search**) (**minimax +  $\alpha\beta$ -Pruning**)
- ▷ Constraint Satisfaction Problems (**heuristic search over partial assignments**)
  - ▷ States as partial variable assignments, transitions as assignment
  - ▷ **Heuristics** informed by current restrictions, constraint graph
  - ▷ Inference as constraint propagation (**transferring possible values across arcs**)
- ▷ Describing world states by formal language (**and drawing inferences**)
  - ▷ Propositional logic and DPLL (**deciding entailment efficiently**)
  - ▷ First-order logic and ATP (**reasoning about infinite domains**)
  - ▷ **Digression:** Logic programming (**logic + search**)
  - ▷ **Description logics** as moderately expressive, but **decidable** logics
- ▷ **Planning:** Problem Solving using white-box world/action descriptions
  - ▷ **Framework:** describing world states in logic as sets of propositions and actions by preconditions and add/delete lists
  - ▷ **Algorithms:** e.g. **heuristic search** by problem relaxations

## Topics of AI-2 (Summer Semester)

- ▷ **Uncertain** Knowledge and Reasoning
  - ▷ **Uncertainty**
  - ▷ **Probabilistic reasoning**
  - ▷ Making Decisions in Episodic Environments
  - ▷ Problem Solving in Sequential Environments
- ▷ Foundations of **machine learning**
  - ▷ Learning from Observations
  - ▷ Knowledge in Learning
  - ▷ Statistical Learning Methods
- ▷ Communication
  - ▷ **Natural Language Processing**
  - ▷ **Natural Language** for Communication

Part VI

Excursions

As this course is predominantly an overview over the topics of [Artificial Intelligence](#), and not about the theoretical underpinnings, we give the discussion about these as a “suggested readings” part here.

# Appendix A

## Completeness of Calculi for Propositional Logic

The next step is to analyze the two **calculi** for **completeness**. For that we will first give ourselves a very powerful tool: the “model existence theorem” (??), which encapsulates the model-theoretic part of **completeness** theorems. With that, completeness proofs – which are quite tedious otherwise – become a breeze.

### A.1 Abstract Consistency and Model Existence

We will now come to an important tool in the theoretical study of reasoning calculi: the “abstract consistency”/“model existence” method. This method for analyzing calculi was developed by Jaako Hintikka, Raymond Smullyan, and Peter Andrews in 1950-1970 as an encapsulation of similar constructions that were used in completeness arguments in the decades before. The basis for this method is Smullyan’s Observation [Smu63] that completeness proofs based on Hintikka sets only certain properties of consistency and that with little effort one can obtain a generalization “Smullyan’s Unifying Principle”.

The basic intuition for this method is the following: typically, a **logical system**  $\mathcal{L} = \langle \mathcal{L}, \mathcal{K}, \models \rangle$  has multiple **calculi**, human-oriented ones like the natural deduction calculi and machine-oriented ones like the automated theorem proving calculi. All of these need to be analyzed for completeness (as a basic quality assurance measure).

A **completeness** proof for a **calculus**  $\mathcal{C}$  for  $\mathcal{S}$  typically comes in two parts: one analyzes  $\mathcal{C}$ -consistency (sets that cannot be refuted in  $\mathcal{C}$ ), and the other construct  $\mathcal{K}$ -models for  $\mathcal{C}$ -consistent sets.

In this situation the “abstract consistency”/“model existence” method encapsulates the model construction process into a meta-theorem: the “model existence” theorem. This provides a set of syntactic (“abstract consistency”) conditions for calculi that are sufficient to construct models.

With the model existence theorem it suffices to show that  $\mathcal{C}$ -consistency is an abstract consistency property (a purely syntactic task that can be done by a  $\mathcal{C}$ -proof transformation argument) to obtain a completeness result for  $\mathcal{C}$ .

#### Model Existence (Overview)

- ▷ **Definition:** Abstract consistency
- ▷ **Definition:** Hintikka set (maximally abstract consistent)
- ▷ **Theorem:** Hintikka sets are satisfiable

- ▷ **Theorem:** If  $\Phi$  is abstract consistent, then  $\Phi$  can be extended to a Hintikka set.
- ▷ **Corollary:** If  $\Phi$  is abstract consistent, then  $\Phi$  is *satisfiable*.
- ▷ **Application:** Let  $\mathcal{C}$  be a *calculus*, if  $\Phi$  is  $\mathcal{C}$ -consistent, then  $\Phi$  is abstract consistent.
- ▷ **Corollary:**  $\mathcal{C}$  is complete.

The proof of the model existence theorem goes via the notion of a Hintikka set, a set of formulae with very strong syntactic closure properties, which allow to read off models. Jaako Hintikka's original idea for completeness proofs was that for every complete *calculus*  $\mathcal{C}$  and every  $\mathcal{C}$ -consistent set one can induce a Hintikka set, from which a model can be constructed. This can be considered as a first model existence theorem. However, the process of obtaining a Hintikka set for a  $\mathcal{C}$ -consistent set  $\Phi$  of sentences usually involves complicated *calculus* dependent constructions.

In this situation, Raymond Smullyan was able to formulate the sufficient conditions for the existence of Hintikka sets in the form of “abstract consistency properties” by isolating the *calculus* independent parts of the Hintikka set construction. His technique allows to reformulate Hintikka sets as maximal elements of abstract consistency classes and interpret the Hintikka set construction as a *maximizing* limit process.

To carry out the “model-existence”/“abstract consistency” method, we will first have to look at the notion of consistency.

*Consistency* and *refutability* are very important notions when studying the *completeness* for *calculi*; they form syntactic counterparts of *satisfiability*.

## Consistency

- ▷ Let  $\mathcal{C}$  be a *calculus*,...
- ▷ **Definition A.1.1.** Let  $\mathcal{C}$  be a *calculus*, then a formula set  $\Phi$  is called  $\mathcal{C}$ -, if there is a *refutation*, i.e. a *derivation* of a *contradiction* from  $\Phi$ . The act of finding a *refutation* for  $\Phi$  is called *refuting*  $\Phi$ .
- ▷ **Definition A.1.2.** We call a *pair* of formulae  $A$  and  $\neg A$  a *contradiction*.
- ▷ So a set  $\Phi$  is  $\mathcal{C}$ -refutable, if  $\mathcal{C}$  can derive a *contradiction* from it.
- ▷ **Definition A.1.3.** Let  $\mathcal{C}$  be a *calculus*, then a formula set  $\Phi$  is called  $\mathcal{C}$ -, iff there is a formula  $B$ , that is not *derivable* from  $\Phi$  in  $\mathcal{C}$ .
- ▷ **Definition A.1.4.** We call a *calculus*  $\mathcal{C}$  *reasonable*, iff implication elimination and conjunction introduction are *admissible* in  $\mathcal{C}$  and  $A \wedge \neg A \Rightarrow B$  is a  $\mathcal{C}$ -theorem.
- ▷ **Theorem A.1.5.**  $\mathcal{C}$ -inconsistency and  $\mathcal{C}$ -refutability coincide for *reasonable calculi*.

It is very important to distinguish the syntactic  $\mathcal{C}$ -refutability and  $\mathcal{C}$ -consistency from *satisfiability*, which is a property of formulae that is at the heart of semantics. Note that the former have the *calculus* (a syntactic device) as a parameter, while the latter does not. In fact we should actually say *S-satisfiability*, where  $\langle \mathcal{L}, \mathcal{K}, \models \rangle$  is the current *logical system*.

Even the word “*contradiction*” has a syntactical flavor to it, it translates to “saying against each other” from its Latin root.

## Abstract Consistency

- ▷ **Definition A.1.6.** Let  $\nabla$  be a collection of sets. We call  $\nabla$  **closed under subsets**, iff for each  $\Phi \in \nabla$ , all subsets  $\Psi \subseteq \Phi$  are elements of  $\nabla$ .
- ▷ **Definition A.1.7 (Notation).** We will use  $\Phi * \mathbf{A}$  for  $\Phi \cup \{\mathbf{A}\}$ .
- ▷ **Definition A.1.8.** A collection  $\nabla$  of sets of propositional formulae is called an **abstract consistency class**, iff it is closed under subsets, and for each  $\Phi \in \nabla$ 
  - $\nabla_c$ )  $P \notin \Phi$  or  $\neg P \notin \Phi$  for  $P \in \mathcal{V}_0$
  - $\nabla_{\neg}$ )  $\neg \neg \mathbf{A} \in \Phi$  implies  $\Phi * \mathbf{A} \in \nabla$
  - $\nabla_{\vee}$ )  $\mathbf{A} \vee \mathbf{B} \in \Phi$  implies  $\Phi * \mathbf{A} \in \nabla$  or  $\Phi * \mathbf{B} \in \nabla$
  - $\nabla_{\wedge}$ )  $\neg(\mathbf{A} \vee \mathbf{B}) \in \Phi$  implies  $\Phi \cup \{\neg \mathbf{A}, \neg \mathbf{B}\} \in \nabla$
- ▷ **Example A.1.9.** The empty set is an abstract consistency class
- ▷ **Example A.1.10.** The set  $\{\emptyset, \{Q\}, \{P \vee Q\}, \{P \vee Q, Q\}\}$  is an abstract consistency class
- ▷ **Example A.1.11.** The family of satisfiable sets is an abstract consistency class.

So a family of sets (we call it a family, so that we do not have to say “set of sets” and we can distinguish the levels) is an abstract consistency class, iff it fulfills five simple conditions, of which the last three are closure conditions.

Think of an abstract consistency class as a family of “consistent” sets (e.g.  $\mathcal{C}$ -consistent for some calculus  $\mathcal{C}$ ), then the properties make perfect sense: They are naturally closed under subsets — if we cannot derive a contradiction from a large set, we certainly cannot from a subset, furthermore,

- $\nabla_c$ ) If both  $P \in \Phi$  and  $\neg P \in \Phi$ , then  $\Phi$  cannot be “consistent”.
- $\nabla_{\neg}$ ) If we cannot derive a contradiction from  $\Phi$  with  $\neg \neg \mathbf{A} \in \Phi$  then we cannot from  $\Phi * \mathbf{A}$ , since they are logically equivalent.

The other two conditions are motivated similarly. We will carry out the proof here, since it gives us practice in dealing with the abstract consistency properties.

The main result here is that abstract consistency classes can be extended to compact ones. The proof is quite tedious, but relatively straightforward. It allows us to assume that all abstract consistency classes are compact in the first place (otherwise we pass to the compact extension).

Actually we are after abstract consistency classes that have an even stronger property than just being closed under subsets. This will allow us to carry out a limit construction in the Hintikka set extension argument later.

## Compact Collections

- ▷ **Definition A.1.12.** We call a collection  $\nabla$  of sets **compact**, iff for any set  $\Phi$  we have  $\Phi \in \nabla$ , iff  $\Psi \in \nabla$  for every finite subset  $\Psi$  of  $\Phi$ .
- ▷ **Lemma A.1.13.** If  $\nabla$  is compact, then  $\nabla$  is closed under subsets.
- ▷ *Proof:*

1. Suppose  $S \subseteq T$  and  $T \in \nabla$ .
2. Every finite subset  $A$  of  $S$  is a finite subset of  $T$ .
3. As  $\nabla$  is compact, we know that  $A \in \nabla$ .
4. Thus  $S \in \nabla$ .

The property of being **closed under subsets** is a “downwards-oriented” property: We go from large sets to small sets, **compactness** (the interesting direction anyways) is also an “upwards-oriented” property. We can go from small (**finite**) sets to large (**infinite**) sets. The main application for the **compactness** condition will be to show that **infinite** sets of formulae are in a **collection**  $\nabla$  by testing all their **finite subsets** (which is much simpler).

## Compact Abstract Consistency Classes

▷ **Lemma A.1.14.** Any abstract consistency class can be extended to a compact one.

▷ *Proof:*

1. We choose  $\nabla' := \{\Phi \subseteq \text{wff}_0(\mathcal{V}_0) \mid \text{every finite subset of } \Phi \text{ is in } \nabla\}$ .
2. Now suppose that  $\Phi \in \nabla$ .  $\nabla$  is **closed under subsets**, so every finite subset of  $\Phi$  is in  $\nabla$  and thus  $\Phi \in \nabla'$ . Hence  $\nabla \subseteq \nabla'$ .
3. Next let us show that each  $\nabla$  is **compact**.
  - 3.1. Suppose  $\Phi \in \nabla'$  and  $\Psi$  is an arbitrary finite subset of  $\Phi$ .
  - 3.2. By definition of  $\nabla'$  all finite subsets of  $\Phi$  are in  $\nabla$  and therefore  $\Psi \in \nabla$ .
  - 3.3. Thus all finite subsets of  $\Phi$  are in  $\nabla$  whenever  $\Phi$  is in  $\nabla'$ .
  - 3.4. On the other hand, suppose all finite subsets of  $\Phi$  are in  $\nabla$ .
  - 3.5. Then by the definition of  $\nabla'$  the finite subsets of  $\Phi$  are also in  $\nabla$ , so  $\Phi \in \nabla$ . Thus  $\nabla'$  is **compact**.
4. Note that  $\nabla'$  is **closed under subsets** by the Lemma above.
5. Now we show that if  $\nabla$  satisfies  $\nabla_*$ , then  $\nabla$  satisfies  $\nabla'_*$ .
  - 5.1. To show  $\nabla_c$ , let  $\Phi \in \nabla'$  and suppose there is an atom  $\mathbf{A}$ , such that  $\{\mathbf{A}, \neg\mathbf{A}\} \subseteq \Phi$ . Then  $\{\mathbf{A}, \neg\mathbf{A}\} \in \nabla$  contradicting  $\nabla_c$ .
  - 5.2. To show  $\nabla_{\neg}$ , let  $\Phi \in \nabla'$  and  $\neg\neg\mathbf{A} \in \Phi$ , then  $\Phi * \mathbf{A} \in \nabla'$ .
    - 5.2.1. Let  $\Psi$  be any finite subset of  $\Phi * \mathbf{A}$ , and  $\Theta := (\Psi \setminus \{\mathbf{A}\}) * \neg\neg\mathbf{A}$ .
    - 5.2.2.  $\Theta$  is a finite subset of  $\Phi$ , so  $\Theta \in \nabla$ .
    - 5.2.3. Since  $\nabla$  is an abstract consistency class and  $\neg\neg\mathbf{A} \in \Theta$ , we get  $\Theta * \mathbf{A} \in \nabla$  by  $\nabla_{\neg}$ .
    - 5.2.4. We know that  $\Psi \subseteq \Theta * \mathbf{A}$  and  $\nabla$  is closed under subsets, so  $\Psi \in \nabla$ .
    - 5.2.5. Thus every finite subset  $\Psi$  of  $\Phi * \mathbf{A}$  is in  $\nabla$  and therefore by definition  $\Phi * \mathbf{A} \in \nabla'$ .
  - 5.3. the other cases are analogous to  $\nabla_{\neg}$ .

Hintikka sets are sets of sentences with very strong analytic closure conditions. These are motivated as maximally consistent sets i.e. sets that already contain everything that can be consistently added to them.

## $\nabla$ -Hintikka Set

▷ **Definition A.1.15.** Let  $\nabla$  be an abstract consistency class, then we call a set  $\mathcal{H} \in \nabla$  a  $\nabla$  **Hintikka Set**, iff  $\mathcal{H}$  is maximal in  $\nabla$ , i.e. for all  $\mathbf{A}$  with  $\mathcal{H} * \mathbf{A} \in \nabla$  we already have  $\mathbf{A} \in \mathcal{H}$ .

▷ **Theorem A.1.16 (Hintikka Properties).** Let  $\nabla$  be an abstract consistency class and  $\mathcal{H}$  be a  $\nabla$ -Hintikka set, then

$\mathcal{H}_c$ ) For all  $\mathbf{A} \in \text{wff}_0(\mathcal{V}_0)$  we have  $\mathbf{A} \notin \mathcal{H}$  or  $\neg \mathbf{A} \notin \mathcal{H}$

$\mathcal{H}_\neg$ ) If  $\neg \neg \mathbf{A} \in \mathcal{H}$  then  $\mathbf{A} \in \mathcal{H}$

$\mathcal{H}_\vee$ ) If  $\mathbf{A} \vee \mathbf{B} \in \mathcal{H}$  then  $\mathbf{A} \in \mathcal{H}$  or  $\mathbf{B} \in \mathcal{H}$

$\mathcal{H}_\wedge$ ) If  $\neg(\mathbf{A} \vee \mathbf{B}) \in \mathcal{H}$  then  $\neg \mathbf{A}, \neg \mathbf{B} \in \mathcal{H}$

## $\nabla$ -Hintikka Set

▷ *Proof:*

We prove the properties in turn

1.  $\mathcal{H}_c$  by induction on the structure of  $\mathbf{A}$

1.1.  $\mathbf{A} \in \mathcal{V}_0$  Then  $\mathbf{A} \notin \mathcal{H}$  or  $\neg \mathbf{A} \notin \mathcal{H}$  by  $\nabla_c$ .

1.2.  $\mathbf{A} = \neg \mathbf{B}$

1.2.1. Let us assume that  $\neg \mathbf{B} \in \mathcal{H}$  and  $\neg \neg \mathbf{B} \in \mathcal{H}$ ,

1.2.2. then  $\mathcal{H} * \mathbf{B} \in \nabla$  by  $\nabla_\neg$ , and therefore  $\mathbf{B} \in \mathcal{H}$  by maximality.

1.2.3. So both  $\mathbf{B}$  and  $\neg \mathbf{B}$  are in  $\mathcal{H}$ , which contradicts the **induction hypothesis**.

1.3.  $\mathbf{A} = \mathbf{B} \vee \mathbf{C}$  similar to the previous case

2. We prove  $\mathcal{H}_\neg$  by maximality of  $\mathcal{H}$  in  $\nabla$ .

2.1. If  $\neg \neg \mathbf{A} \in \mathcal{H}$ , then  $\mathcal{H} * \mathbf{A} \in \nabla$  by  $\nabla_\neg$ .

2.2. The maximality of  $\mathcal{H}$  now gives us that  $\mathbf{A} \in \mathcal{H}$ .

Proof sketch: other  $\mathcal{H}_*$  are similar

The following theorem is one of the main results in the “abstract consistency”/“model existence” method. For any abstract consistent set  $\Phi$  it allows us to construct a Hintikka set  $\mathcal{H}$  with  $\Phi \in \mathcal{H}$ .

## Extension Theorem

▷ **Theorem A.1.17.** If  $\nabla$  is an abstract consistency class and  $\Phi \in \nabla$ , then there is a  $\nabla$ -Hintikka set  $\mathcal{H}$  with  $\Phi \subseteq \mathcal{H}$ .

▷ *Proof:*

1. **Wlog.** we assume that  $\nabla$  is **compact** (otherwise pass to compact extension)

2. We choose an **enumeration**  $\mathbf{A}_1, \dots$  of the set  $\text{wff}_0(\mathcal{V}_0)$

3. and construct a sequence of sets  $\mathbf{H}_i$  with  $\mathbf{H}_0 := \Phi$  and

$$\mathbf{H}_{n+1} := \begin{cases} \mathbf{H}_n & \text{if } \mathbf{H}_n * \mathbf{A}_n \notin \nabla \\ \mathbf{H}_n * \mathbf{A}_n & \text{if } \mathbf{H}_n * \mathbf{A}_n \in \nabla \end{cases}$$

4. Note that all  $\mathbf{H}_i \in \nabla$ , choose  $\mathcal{H} := \bigcup_{i \in \mathbb{N}} \mathbf{H}_i$

5.  $\Psi \subseteq \mathcal{H}$  finite implies there is a  $j \in \mathbb{N}$  such that  $\Psi \subseteq \mathbf{H}_j$ ,
6. so  $\Psi \in \nabla$  as  $\nabla$  is closed under subsets and  $\mathcal{H} \in \nabla$  as  $\nabla$  is compact.
7. Let  $\mathcal{H} * \mathbf{B} \in \nabla$ , then there is a  $j \in \mathbb{N}$  with  $\mathbf{B} = \mathbf{A}_j$ , so that  $\mathbf{B} \in \mathbf{H}_{j+1}$  and  $\mathbf{H}_{j+1} \subseteq \mathcal{H}$
8. Thus  $\mathcal{H}$  is  $\nabla$ -maximal

Note that the construction in the proof above is non-trivial in two respects. First, the limit construction for  $\mathcal{H}$  is not executed in our original abstract consistency class  $\nabla$ , but in a suitably extended one to make it compact — the original would not have contained  $\mathcal{H}$  in general. Second, the set  $\mathcal{H}$  is not unique for  $\Phi$ , but depends on the choice of the enumeration of  $\text{wff}_0(\mathcal{V}_0)$ . If we pick a different enumeration, we will end up with a different  $\mathcal{H}$ . Say if  $\mathbf{A}$  and  $\neg\mathbf{A}$  are both  $\nabla$ -consistent<sup>1</sup> with  $\Phi$ , then depending on which one is first in the enumeration  $\mathcal{H}$ , will contain that one; with all the consequences for subsequent choices in the construction process.

## Valuation

- ▷ **Definition A.1.18.** A function  $\nu: \text{wff}_0(\mathcal{V}_0) \rightarrow \mathcal{D}_o$  is called a **valuation**, iff
  - ▷  $\nu(\neg\mathbf{A}) = \mathbf{T}$ , iff  $\nu(\mathbf{A}) = \mathbf{F}$
  - ▷  $\nu(\mathbf{A} \wedge \mathbf{B}) = \mathbf{T}$ , iff  $\nu(\mathbf{A}) = \mathbf{T}$  and  $\nu(\mathbf{B}) = \mathbf{T}$
- ▷ **Lemma A.1.19.** If  $\nu: \text{wff}_0(\mathcal{V}_0) \rightarrow \mathcal{D}_o$  is a valuation and  $\Phi \subseteq \text{wff}_0(\mathcal{V}_0)$  with  $\nu(\Phi) = \{\mathbf{T}\}$ , then  $\Phi$  is *satisfiable*.
- ▷ *Proof sketch:*  $\nu|_{\mathcal{V}_0}: \mathcal{V}_0 \rightarrow \mathcal{D}_o$  is a satisfying variable assignment.
- ▷ **Lemma A.1.20.** If  $\varphi: \mathcal{V}_0 \rightarrow \mathcal{D}_o$  is a variable assignment, then  $\mathcal{I}_\varphi: \text{wff}_0(\mathcal{V}_0) \rightarrow \mathcal{D}_o$  is a valuation.

Now, we only have to put the pieces together to obtain the model existence theorem we are after.

## Model Existence

- ▷ **Lemma A.1.21 (Hintikka-Lemma).** If  $\nabla$  is an abstract consistency class and  $\mathcal{H}$  a  $\nabla$ -Hintikka set, then  $\mathcal{H}$  is *satisfiable*.
- ▷ *Proof:*
  1. We define  $\nu(\mathbf{A}) := \mathbf{T}$ , iff  $\mathbf{A} \in \mathcal{H}$
  2. then  $\nu$  is a valuation by the Hintikka properties
  3. and thus  $\nu|_{\mathcal{V}_0}$  is a satisfying assignment.
- ▷ **Theorem A.1.22 (Model Existence).** If  $\nabla$  is an abstract consistency class and  $\Phi \in \nabla$ , then  $\Phi$  is *satisfiable*.
- Proof:*
  - ▷ 1. There is a  $\nabla$ -Hintikka set  $\mathcal{H}$  with  $\Phi \subseteq \mathcal{H}$  (Extension Theorem)
  - 2. We know that  $\mathcal{H}$  is *satisfiable*. (Hintikka-Lemma)
  - 3. In particular,  $\Phi \subseteq \mathcal{H}$  is *satisfiable*.

<sup>1</sup>EDNOTE: introduce this above

## A.2 A Completeness Proof for Propositional Tableaux

With the model existence proof we have introduced in the last section, the completeness proof for first-order natural deduction is rather simple, we only have to check that Tableaux-consistency is an abstract consistency property.

We encapsulate all of the technical difficulties of the problem in a technical Lemma. From that, the completeness proof is just an application of the high-level theorems we have just proven.

### Abstract Completeness for $\mathcal{T}_0$

---

▷ **Lemma A.2.1.**  $\{\Phi \mid \Phi^\top \text{ has no closed tableau}\}$  is an abstract consistency class.

▷ *Proof:* Let's call the set above  $\nabla$

*We have to convince ourselves of the abstract consistency properties*

1.  $\nabla_c P, \neg P \in \Phi$  implies  $P^F, P^\top \in \Phi^\top$ .
2.  $\nabla_\neg$  Let  $\neg\neg A \in \Phi$ .
  - 2.1. For the proof of the contrapositive we assume that  $\Phi * A$  has a closed tableau  $\mathcal{T}$  and show that already  $\Phi$  has one:
  - 2.2. applying each of  $\mathcal{T}_0 \neg^\top$  and  $\mathcal{T}_0 \neg^F$  once allows to extend any tableau with  $\neg\neg B^\alpha$  by  $B^\alpha$ .
  - 2.3. any path in  $\mathcal{T}$  that is closed with  $\neg\neg A^\alpha$ , can be closed by  $A^\alpha$ .
3.  $\nabla_\vee$  Suppose  $A \vee B \in \Phi$  and both  $\Phi * A$  and  $\Phi * B$  have closed tableaux
  - 3.1. consider the tableaux:
 

$\Phi^\top$	$\Phi^\top$	$\Psi^\top$
$A^\top$	$B^\top$	$(A \vee B)^\top$
$Rest^1$	$Rest^2$	$A^\top \mid B^\top$
		$Rest^1 \mid Rest^2$
4.  $\nabla_\wedge$  suppose,  $\neg(A \vee B) \in \Phi$  and  $\Phi \{ \neg A, \neg B \}$  have closed tableau  $\mathcal{T}$ .
  - 4.1. We consider
 

$\Phi^\top$	$\Psi^\top$
$A^F$	$(A \vee B)^F$
$B^F$	$A^F$
$Rest$	$B^F$
	$Rest$

where  $\Phi = \Psi * \neg(A \vee B)$ .

---

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 689 2024-02-08

**Observation:** If we look at the completeness proof below, we see that the Lemma above is the only place where we had to deal with specific properties of the  $\mathcal{T}_0$ .

So if we want to prove completeness of any other calculus with respect to propositional logic, then we only need to prove an analogon to this lemma and can use the rest of the machinery we have already established “off the shelf”.

This is one great advantage of the “abstract consistency method”; the other is that the method can be extended transparently to other logics.

### Completeness of $\mathcal{T}_0$

---

▷ **Corollary A.2.2.**  $\mathcal{T}_0$  is *complete*.

▷ *Proof:* by contradiction

1. We assume that  $\mathbf{A} \in \text{wff}_0(\mathcal{V}_0)$  is *valid*, but there is no *closed tableau* for  $\mathbf{A}^F$ .
2. We have  $\{\neg \mathbf{A}\} \in \nabla$  as  $\neg \mathbf{A}^T = \mathbf{A}^F$ .
3. so  $\neg \mathbf{A}$  is *satisfiable* by the model existence theorem (which is applicable as  $\nabla$  is an *abstract consistency class* by our Lemma above)
4. this contradicts our assumption that  $\mathbf{A}$  is *valid*.

## Conflict Driven Clause Learning

### B.1 Why Did Unit Propagation Yield a Conflict?

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/27026>.

**DPLL: Example (Redundance1)**

▷ **Example B.1.1.** We introduce some nasty redundance to make DPLL slow.  
 $\Delta := (P^F \vee Q^F \vee R^T ; P^F \vee Q^F \vee R^F ; P^F \vee Q^T \vee R^T ; P^F \vee Q^T \vee R^F)$   
DPLL on  $\Delta ; \Theta$  with  $\Theta := (X_1^T \vee \dots \vee X_n^T ; X_1^F \vee \dots \vee X_n^F)$

FAU FRIEDRICH-ALEXANDER UNIVERSITÄT ERLANGEN-NÜRNBERG Michael Kohlhase: Artificial Intelligence 1 691 2024-02-08

**How To *Not* Make the Same Mistakes Over Again?**

▷ **It's not that difficult, really:**

- (A) Figure out what went wrong.
- (B) Learn to not do that again in the future.

▷ **And now for DPLL:**

- (A) Why did **unit propagation** yield a Conflict?

- ▷ This Section. We will capture the “what went wrong” in terms of graphs over **literals** set during the search, and their dependencies.

▷ **What can we learn from that information?:**

- ▷ A new **clause!** Next section.

## Implication Graphs for DPLL

- ▷ **Definition B.1.2.** Let  $\beta$  be a **branch** in a **DPLL derivation** and  $P$  a variable on  $\beta$  then we call

- ▷  $P^\alpha$  a **choice literal** if its **value** is set to  $\alpha$  by the **splitting rule**.
- ▷  $P^\alpha$  an **implied literal**, if the **value** of  $P$  is set to  $\alpha$  by the **UP rule**.
- ▷  $P^\alpha$  a **conflict literal**, if it contributes to a **derivation** of the **empty clause**.

- ▷ **Definition B.1.3 (Implication Graph).**

Let  $\Delta$  be a **clause set**,  $\beta$  a **DPLL search branch** on  $\Delta$ . The **implication graph**  $G_\beta^{\text{impl}}$  is the **directed graph** whose **vertices** are labeled with the **choice and implied literals** along  $\beta$ , as well as a separate **conflict vertex**  $\square_C$  for every **clause**  $C$  that became **empty** on  $\beta$ .

Wherever a **clause**  $l_1, \dots, l_k \vee l' \in \Delta$  became **unit** with **implied literal**  $l'$ ,  $G_\beta^{\text{impl}}$  includes the **edges**  $(\bar{l}_i, l')$ .

Where  $C = l_1 \vee \dots \vee l_k \in \Delta$  became **empty**,  $G_\beta^{\text{impl}}$  includes the **edges**  $(\bar{l}_i, \square_C)$ .

- ▷ **Question:** How do we know that  $\bar{l}_i$  are **vertices** in  $G_\beta^{\text{impl}}$ ?
- ▷ **Answer:** Because  $l_1 \vee \dots \vee l_k \vee l'$  became **unit/empty**.
- ▷ **Observation B.1.4.**  $G_\beta^{\text{impl}}$  is **acyclic**.
- ▷ *Proof sketch:* **UP** can't **derive**  $l'$  whose **value** was already set beforehand.
- ▷ **Intuition:** The **initial vertices** are the **choice literals** and **unit clauses** of  $\Delta$ .

## Implication Graphs: Example (Vanilla1) in Detail

- ▷ **Example B.1.5.** Let  $\Delta := (P^T \vee Q^T \vee R^F ; P^F \vee Q^F ; R^T ; P^T \vee Q^F)$ .

We look at the left **branch** of the **derivation** from Example 13.2.2:

### Implication Graphs: Example (Redundance2)

▷ **Example B.1.7.** Continuing from Example B.1.1:

$$\Delta := P^F \vee Q^F \vee R^T; P^F \vee Q^F \vee R^F; P^F \vee Q^T \vee R^T; P^F \vee Q^T \vee R^F$$

$$\Theta := X_1^T \vee \dots \vee X_n^T; X_1^F \vee \dots \vee X_n^F$$

DPLL on  $\Delta; \Theta; \Phi$  with  $\Phi := (Q^F \vee S^T; Q^F \vee S^F)$   
 Choice literals:  $P^T, (X_1^T), \dots, (X_n^T), Q^T$ . Implied literals:

### Implication Graphs: A Remark

- ▷ The **implication graph** is *not* uniquely determined by the **Choice literals**.
- ▷ It depends on “ordering decisions” during **UP**: Which **unit clause** is picked first.
- ▷ **Example B.1.8.**  $\Delta = P^F \vee Q^F; Q^T; P^T$

### Conflict Graphs

- ▷ A **conflict graph** captures “what went wrong” in a failed node.
- ▷ **Definition B.1.9 (Conflict Graph).** Let  $\Delta$  be a **clause set**, and let  $G_\beta^{impl}$  be the **implication graph** for some search **branch**  $\beta$  of DPLL on  $\Delta$ . A subgraph  $C$  of  $G_\beta^{impl}$  is a **conflict graph** if:
  - (i)  $C$  contains exactly one **conflict vertex**  $\square_C$ .

- (ii) If  $l'$  is a vertex in  $C$ , then all parents of  $l'$ , i.e. vertices  $\bar{l}_i$  with a  $I$  edge  $(\bar{l}_i, l')$ , are vertices in  $C$  as well.
  - (iii) All vertices in  $C$  have a path to  $\square_C$ .
- ▷ Conflict graph  $\hat{=}$  Starting at a conflict vertex, backchain through the implication graph until reaching choice literals.

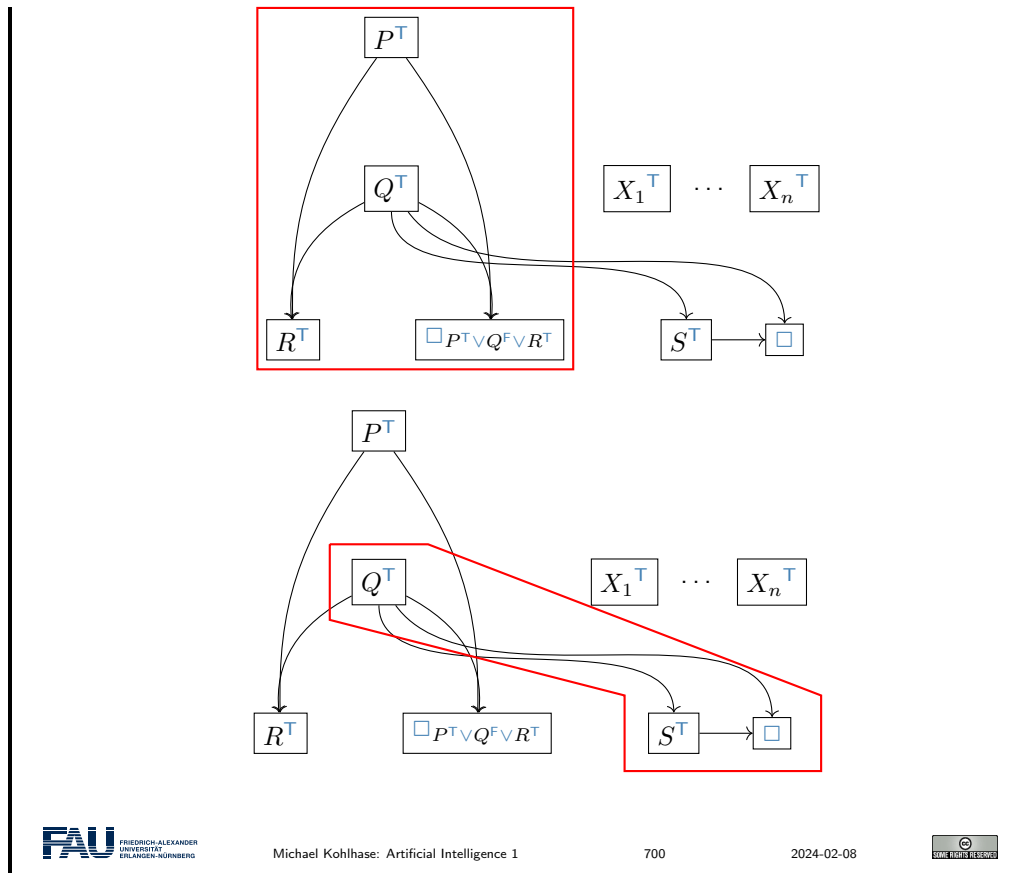

### Conflict-Graphs: Example (Redundance1)

- ▷ **Example B.1.10.** Continuing from Example B.1.6:  $\Delta := (P^F \vee Q^F \vee R^T; P^F \vee Q^F \vee R^F; P^F \vee Q^T \vee R^T; P^F \vee Q^T \vee R^F)$   
 DPLL on  $\Delta; \Theta$  with  $\Theta := (X_1^T \vee \dots \vee X_{100}^T; X_1^F \vee \dots \vee X_{100}^F)$   
 Choice literals:  $P^T, (X_1^T), \dots, (X_{100}^T), Q^T$ . Implied literals:  $R^T$ .

### Conflict Graphs: Example (Redundance2)

- ▷ **Example B.1.11.** Continuing from Example B.1.7 and Example B.1.10:
- $$\Delta := P^F \vee Q^F \vee R^T; P^F \vee Q^F \vee R^F; P^F \vee Q^T \vee R^T; P^F \vee Q^T \vee R^F$$
- $$\Theta := X_1^T \vee \dots \vee X_n^T; X_1^F \vee \dots \vee X_n^F$$
- DPLL on  $\Delta; \Theta; \Phi$  with  $\Phi := (Q^F \vee S^T; Q^F \vee S^F)$   
 Choice literals:  $P^T, (X_1^T), \dots, (X_n^T), Q^T$ . Implied literals:  $R^T$ .

## B.2 Clause Learning

### Clause Learning

- ▷ **Observation:** Conflict graphs encode the entailment relation.
- ▷ **Definition B.2.1.** Let  $\Delta$  be a clause set,  $C$  be a conflict graph at some time point during a run of DPLL on  $\Delta$ , and  $L$  be the choice literals in  $C$ , then we call  $c := \bigvee_{l \in L} \bar{l}$  the learned clause for  $C$ .
- ▷ **Theorem B.2.2.** Let  $\Delta$ ,  $C$ , and  $c$  as in Definition B.2.1, then  $\Delta \models c$ .
- ▷ **Idea:** We can add learned clauses to DPLL derivations at any time without losing soundness. (maybe this helps, if we have a good notion of learned clauses)
- ▷ **Definition B.2.3.** Clause learning is the process of adding learned clauses to DPLL clause sets at specific points. (details coming up)

### Clause Learning: Example (Redundance1)

- ▷ **Example B.2.4.** Continuing from Example B.1.10:

$\Delta := (P^F \vee Q^F \vee R^T; P^F \vee Q^F \vee R^F; P^F \vee Q^T \vee R^T; P^F \vee Q^T \vee R^F)$   
 DPLL on  $\Delta$ ;  $\Theta$  with  $\Theta := (X_1^T \vee \dots \vee X_n^T; X_1^F \vee \dots \vee X_n^F)$   
 Choice literals:  $P^T, (X_1^T), \dots, (X_n^T), Q^T$ . Implied literals:  $R^T$ .

Learned clause:  $P^F \vee Q^F$

## The Effect of Learned Clauses (in Redundance1)

- ▷ What happens after we learned a new clause  $C$ ?
  1. We add  $C$  into  $\Delta$ . e.g.  $C = P^F \vee Q^F$ .
  2. We retract the last choice  $l'$ . e.g. the choice  $l' = Q$ .
- ▷ **Observation:** Let  $C$  be a learned clause, i.e.  $C = \bigvee_{l \in L} \bar{l}$ , where  $L$  is the set of conflict literals in a conflict graph  $G$ .  
 Before we learn  $C$ ,  $G$  must contain the most recent choice  $l'$ : otherwise, the conflict would have occurred earlier on.  
 So  $C = l_1^T \vee \dots \vee l_k^T \vee \bar{l}'$  where  $l_1, \dots, l_k$  are earlier choices.
- ▷ **Example B.2.5.**  $l_1 = P$ ,  $C = P^F \vee Q^F$ ,  $l' = Q$ .
- ▷ **Observation:** Given the earlier choices  $l_1, \dots, l_k$ , after we learned the new clause  $C = \bar{l}_1 \vee \dots \vee \bar{l}_k \vee \bar{l}'$ , the value of  $\bar{l}'$  is now set by UP!
- ▷ So we can continue:
  3. We set the opposite choice  $\bar{l}'$  as an implied literal.  
 e.g.  $Q^F$  as an implied literal.
  4. We run UP and analyze conflicts.  
 Learned clause: earlier choices only! e.g.  $C = P^F$ , see next slide.

## The Effect of Learned Clauses: Example (Redundance1)

▷ **Example B.2.6.** Continuing from Example B.2.4:

$$\Delta := P^F \vee Q^F \vee R^T; P^F \vee Q^F \vee R^F; P^F \vee Q^T \vee R^T; P^F \vee Q^T \vee R^F$$

$$\Theta := X_1^T \vee \dots \vee X_{100}^T; X_1^F \vee \dots \vee X_{100}^F$$

DPLL on  $\Delta; \Theta; \Phi$  with  $\Phi := (P^F \vee Q^F)$   
 Choice literals:  $P^T, (X_1^T), \dots, (X_{100}^T), Q^T$ . Implied literals:  $Q^F, R^T$ .

Learned clause:  $P^F$

### NOT the same Mistakes over Again: (Redundance1)

▷ **Example B.2.7.** Continuing from Example B.1.10:

$$\Delta := (P^F \vee Q^F \vee R^T; P^F \vee Q^F \vee R^F; P^F \vee Q^T \vee R^T; P^F \vee Q^T \vee R^F)$$

DPLL on  $\Delta; \Theta$  with  $\Theta := (X_1^T \vee \dots \vee X_n^T; X_1^F \vee \dots \vee X_n^F)$

▷ **Note:** Here, the problem could be avoided by **splitting** over different variables.

▷ **Problem:** This is not so in general! (see next slide)

## Clause Learning vs. Resolution

- ▷ **Recall:**  $DPLL \hat{=} \text{tree resolution}$  (from slide 395)
  1. **in particular:** each **derived clause**  $C$  (not in  $\Delta$ ) is **derived** anew every time it is used.
  2. **Problem:** there are  $\Delta$  whose shortest **tree resolution** proof is **exponentially** longer than their shortest (general) **resolution proof**.
- ▷ **Good News:** This is no longer the case with **clause learning**!
  1. We add each **learned clause**  $C$  to  $\Delta$ , can use it as often as we like.
  2. **Clause learning** renders **DPLL** equivalent to **full resolution** [BKS04; PD09]. (In-howfar exactly this is the case was an open question for ca. 10 years, so it's not as easy as I made it look here ...)
- ▷ **In particular:** Selecting different variables/values to split on can *provably* not bring **DPLL** up to the power of **DPLL+Clause Learning**. (cf. slide 705, and previous slide)

## “DPLL + Clause Learning”?

- ▷ **Disclaimer:** We have only seen *how to learn a clause from a conflict*.
- ▷ We will *not* cover how the overall **DPLL algorithm** changes, given this learning. Slides 703 – 705 are merely meant to give a *rough intuition* on “backjumping”.
- ▷ **Definition B.2.8 (Just for the record).** (not exam or exercises relevant)
  - ▷ One *could* run “**DPLL + Clause Learning**” by always **backtracking** to the maximal-level choice variable contained in the **learned clause**.
  - ▷ The actual **algorithm** is called **Conflict Directed Clause Learning (CDCL)**, and differs from **DPLL** more radically:

```

let $L := 0$; $I := \emptyset$
repeat
 execute UP
 if a conflict was reached then /* learned clause $C = \bar{l}_1 \vee \dots \vee \bar{l}_k \vee \bar{l}^*$ /
 if $L = 0$ then return UNSAT
 $L := \max_{i=1}^k \text{level}(l_i)$; erase I below L
 add C into Δ ; add \bar{l}^* to I at level L
 else
 if I is a total interpretation then return I
 choose a new decision literal l ; add l to I at level L
 $L := L + 1$

```

### Remarks

- ▷ **Which clause(s) to learn?:**
  - ▷ While we only select **choice literals**, much more can be done.
  - ▷ For any cut through the **conflict graph**, with **Choice literals** on the “left hand” side of the cut and the **conflict literals** on the right-hand side, the **literals** on the left border of the cut yield a **learnable clause**.
  - ▷ Must take care to *not learn too many clauses* ...
- ▷ **Origins of clause learning:**
  - ▷ **Clause learning** originates from “explanation-based (no-good) learning” developed in the CSP community.
  - ▷ The distinguishing feature here is that the “no-good” is a **clause**:
    - ▷ The exact same type of constraint as the rest of  $\Delta$ .

 Michael Kohlhase: Artificial Intelligence 1

## B.3 Phase Transitions: Where the *Really* Hard Problems Are

A **Video Nugget** covering this section can be found at <https://fau.tv/clip/id/25088>.

### Where Are the Hard Problems?

- ▷ **SAT** is **NP** hard. Worst case for **DPLL** is  $\mathcal{O}(2^n)$ , with  $n$  propositions.
- ▷ Imagine I gave you as homework to make a formula family  $\{\varphi\}$  where **DPLL running time** necessarily is in the order of  $\mathcal{O}(2^n)$ .
  - ▷ I promise you're not gonna find this easy ... (although it is of course possible: e.g., the “Pigeon Hole Problem”).
- ▷ People noticed by the early 90s that, in practice, the **DPLL** worst case does not tend to happen.
- ▷ Modern **SAT solvers** successfully tackle practical instances where  $n > 1.000.000$ .

 Michael Kohlhase: Artificial Intelligence 1

2024-02-08

### Where Are the Hard Problems?

- ▷ **So, what's the problem:** Science is about *understanding the world*.
  - ▷ Are “hard cases” just pathological outliers?
  - ▷ Can we say something about the *typical case*?
- ▷ **Difficulty 1:** What is the “typical case” in applications? E.g., what is the “average” **hardware verification** instance?

- ▷ Consider precisely defined random distributions instead.
- ▷ **Difficulty 2:** Search trees get very complex, and are difficult to analyze *mathematically*, even in trivial examples. Never mind examples of practical relevance ...
- ▷ The most successful works are empirical. (Interesting theory is mainly concerned with *hand-crafted* formulas, like the Pigeon Hole Problem.)

## Phase Transitions in SAT [MSL92]

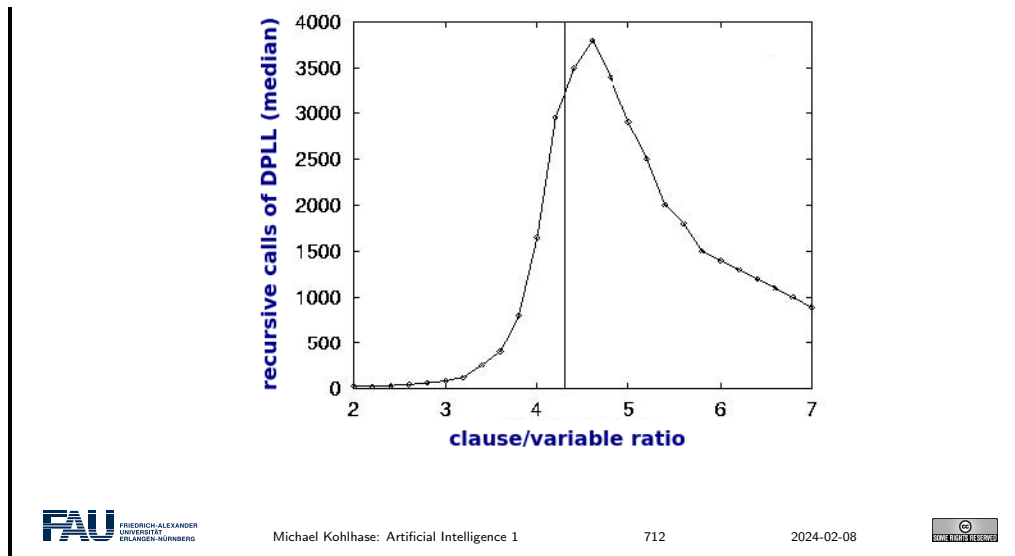

- ▷ **Fixed clause length model:** Fix *clause* length  $k$ ;  $n$  variables.  
Generate  $m$  *clauses*, by uniformly choosing  $k$  *variables*  $P$  for each *clause*  $C$ , and for each *variable*  $P$  deciding uniformly whether to add  $P$  or  $P^F$  into  $C$ .
- ▷ **Order parameter:** Clause/variable ratio  $\frac{m}{n}$ .
- ▷ **Phase transition:** (Fixing  $k = 3$ ,  $n = 50$ )

## Does DPLL Care?

- ▷ **Oh yes, it does:** Extreme *running time* peak at the *phase transition*!

## Why Does DPLL Care?

### ▷ Intuition:

**Under-Constrained:** Satisfiability likelihood close to 1. Many solutions, first DPLL search path usually successful. (“Deep but narrow”)

**Over-Constrained:** Satisfiability likelihood close to 0. Most DPLL search paths short, conflict reached after few applications of splitting rule. (“Broad but shallow”)

**Critically Constrained:** At the phase transition, many *almost-successful* DPLL search paths. (“Close, but no cigar”)

## The Phase Transition Conjecture

▷ **Definition B.3.1.** We say that a class  $P$  of problems exhibits a **phase transition**, if there is an **order parameter**  $o$ , i.e. a structural parameter of  $P$ , so that almost all the hard problems of  $P$  cluster around a **critical value**  $c$  of  $o$  and  $c$  separates one region of the problem space from another, e.g. over-constrained and under-constrained regions.

▷ All NP-complete problems exhibit at least one **phase transition**.

▷ [CKT91] confirmed this for Graph Coloring and Hamiltonian Circuits. Later work confirmed it for SAT (see previous slides), and for numerous other NP-complete problems.

## Why Should We Care?

▷ **Enlightenment:**

- ▷ **Phase transitions** contribute to the fundamental understanding of the behavior of search, even if it's only in random distributions.
- ▷ There are interesting theoretical connections to **phase transition** phenomena in physics. (See [GS05] for a short summary.)

▷ **Ok, but what can we use these results for?:**

- ▷ **Benchmark design:** Choose instances from **phase transition** region.
  - ▷ Commonly used in competitions etc. (In **SAT**, random **phase transition** formulas are the most difficult for **DPLL** style searches.)
  - ▷ **Predicting solver performance:** Yes, but very limited because:
- ▷ All this works only for the particular considered *distributions of instances*! Not meaningful for any other instances.

## Appendix C

# Completeness of Calculi for First-Order Logic

We will now analyze the first-order calculi for completeness. Just as in the case of the propositional calculi, we prove a model existence theorem for the first-order model theory and then use that for the completeness proofs<sup>2</sup>. The proof of the first-order model existence theorem is completely analogous to the propositional one; indeed, apart from the model construction itself, it is just an extension by a treatment for the first-order quantifiers.<sup>3</sup>

EdN:2

EdN:3

### C.1 Abstract Consistency and Model Existence

We will now come to an important tool in the theoretical study of reasoning calculi: the “abstract consistency”/“model existence” method. This method for analyzing calculi was developed by Jaako Hintikka, Raymond Smullyan, and Peter Andrews in 1950-1970 as an encapsulation of similar constructions that were used in completeness arguments in the decades before. The basis for this method is Smullyan’s Observation [Smu63] that completeness proofs based on Hintikka sets only certain properties of consistency and that with little effort one can obtain a generalization “Smullyan’s Unifying Principle”.

The basic intuition for this method is the following: typically, a **logical system**  $\mathcal{L} = \langle \mathcal{L}, \mathcal{K}, \models \rangle$  has multiple **calculi**, human-oriented ones like the natural deduction calculi and machine-oriented ones like the automated theorem proving calculi. All of these need to be analyzed for completeness (as a basic quality assurance measure).

A **completeness** proof for a **calculus**  $\mathcal{C}$  for  $\mathcal{S}$  typically comes in two parts: one analyzes  $\mathcal{C}$ -consistency (sets that cannot be refuted in  $\mathcal{C}$ ), and the other construct  $\mathcal{K}$ -models for  $\mathcal{C}$ -consistent sets.

In this situation the “abstract consistency”/“model existence” method encapsulates the model construction process into a meta-theorem: the “model existence” theorem. This provides a set of syntactic (“abstract consistency”) conditions for calculi that are sufficient to construct models.

With the model existence theorem it suffices to show that  $\mathcal{C}$ -consistency is an abstract consistency property (a purely syntactic task that can be done by a  $\mathcal{C}$ -proof transformation argument) to obtain a completeness result for  $\mathcal{C}$ .

#### Model Existence (Overview)

▷ **Definition:** Abstract consistency

<sup>2</sup>EdNOTE: reference the theorems

<sup>3</sup>EdNOTE: MK: what about equality?

- ▷ **Definition:** Hintikka set (maximally abstract consistent)
- ▷ **Theorem:** Hintikka sets are satisfiable
- ▷ **Theorem:** If  $\Phi$  is abstract consistent, then  $\Phi$  can be extended to a Hintikka set.
- ▷ **Corollary:** If  $\Phi$  is abstract consistent, then  $\Phi$  is *satisfiable*.
- ▷ **Application:** Let  $\mathcal{C}$  be a *calculus*, if  $\Phi$  is  $\mathcal{C}$ -consistent, then  $\Phi$  is abstract consistent.
- ▷ **Corollary:**  $\mathcal{C}$  is complete.

The proof of the model existence theorem goes via the notion of a Hintikka set, a set of formulae with very strong syntactic closure properties, which allow to read off models. Jaako Hintikka's original idea for completeness proofs was that for every complete *calculus*  $\mathcal{C}$  and every  $\mathcal{C}$ -consistent set one can induce a Hintikka set, from which a model can be constructed. This can be considered as a first model existence theorem. However, the process of obtaining a Hintikka set for a  $\mathcal{C}$ -consistent set  $\Phi$  of sentences usually involves complicated *calculus* dependent constructions.

In this situation, Raymond Smullyan was able to formulate the sufficient conditions for the existence of Hintikka sets in the form of “abstract consistency properties” by isolating the *calculus* independent parts of the Hintikka set construction. His technique allows to reformulate Hintikka sets as maximal elements of abstract consistency classes and interpret the Hintikka set construction as a *maximizing* limit process.

To carry out the “model-existence”/“abstract consistency” method, we will first have to look at the notion of consistency.

*Consistency* and *refutability* are very important notions when studying the *completeness* for *calculi*; they form syntactic counterparts of *satisfiability*.

## Consistency

- ▷ Let  $\mathcal{C}$  be a *calculus*,...
- ▷ **Definition C.1.1.** Let  $\mathcal{C}$  be a *calculus*, then a formula set  $\Phi$  is called  $\mathcal{C}$ -, if there is a *refutation*, i.e. a *derivation* of a *contradiction* from  $\Phi$ . The act of finding a *refutation* for  $\Phi$  is called *refuting*  $\Phi$ .
- ▷ **Definition C.1.2.** We call a *pair* of formulae  $A$  and  $\neg A$  a *contradiction*.
- ▷ So a set  $\Phi$  is  $\mathcal{C}$ -*refutable*, if  $\mathcal{C}$  can derive a *contradiction* from it.
- ▷ **Definition C.1.3.** Let  $\mathcal{C}$  be a *calculus*, then a formula set  $\Phi$  is called  $\mathcal{C}$ -, iff there is a formula  $B$ , that is not *derivable* from  $\Phi$  in  $\mathcal{C}$ .
- ▷ **Definition C.1.4.** We call a *calculus*  $\mathcal{C}$  *reasonable*, iff implication elimination and conjunction introduction are *admissible* in  $\mathcal{C}$  and  $A \wedge \neg A \Rightarrow B$  is a  $\mathcal{C}$ -theorem.
- ▷ **Theorem C.1.5.**  $\mathcal{C}$ -inconsistency and  $\mathcal{C}$ -refutability coincide for *reasonable calculi*.

It is very important to distinguish the syntactic  $\mathcal{C}$ -refutability and  $\mathcal{C}$ -consistency from *satisfiability*, which is a property of formulae that is at the heart of semantics. Note that the former have the *calculus* (a syntactic device) as a parameter, while the latter does not. In fact we should actually say  $\mathcal{S}$ -satisfiability, where  $\langle \mathcal{L}, \mathcal{K}, \models \rangle$  is the current *logical system*.

Even the word “**contradiction**” has a syntactical flavor to it, it translates to “saying against each other” from its Latin root.

The notion of an “abstract consistency class” provides the a **calculus**-independent notion of **consistency**: A set  $\Phi$  of sentences is considered “consistent in an abstract sense”, iff it is a member of an abstract consistency class  $\nabla$ .

## Abstract Consistency

▷ **Definition C.1.6.** Let  $\nabla$  be a **collection** of sets. We call  $\nabla$  **closed under subsets**, iff for each  $\Phi \in \nabla$ , all **subsets**  $\Psi \subseteq \Phi$  are **elements** of  $\nabla$ .

▷ **Notation:** We will use  $\Phi * \mathbf{A}$  for  $\Phi \cup \{\mathbf{A}\}$ .

▷ **Definition C.1.7.** A family  $\nabla \subseteq \text{wff}_o(\Sigma_i, \mathcal{V}_i)$  of sets of formulae is called a (first-order) **abstract consistency class**, iff it is **closed under subsets**, and for each  $\Phi \in \nabla$

$\nabla_c$ )  $\mathbf{A} \notin \Phi$  or  $\neg \mathbf{A} \notin \Phi$  for **atomic**  $\mathbf{A} \in \text{wff}_o(\Sigma_i, \mathcal{V}_i)$ .

$\nabla_{\neg}$ )  $\neg \neg \mathbf{A} \in \Phi$  implies  $\Phi * \mathbf{A} \in \nabla$

$\nabla_{\wedge}$ )  $\mathbf{A} \wedge \mathbf{B} \in \Phi$  implies  $\Phi \cup \{\mathbf{A}, \mathbf{B}\} \in \nabla$

$\nabla_{\neg\wedge}$ )  $\neg(\mathbf{A} \wedge \mathbf{B}) \in \Phi$  implies  $\Phi * \neg \mathbf{A} \in \nabla$  or  $\Phi * \neg \mathbf{B} \in \nabla$

$\nabla_{\forall}$ ) If  $\forall X. \mathbf{A} \in \Phi$ , then  $\Phi * ([\mathbf{B}/X](\mathbf{A})) \in \nabla$  for each closed term  $\mathbf{B}$ .

$\nabla_{\exists}$ ) If  $\neg(\forall X. \mathbf{A}) \in \Phi$  and  $c$  is an individual constant that does not occur in  $\Phi$ , then  $\Phi * \neg([c/X](\mathbf{A})) \in \nabla$

The conditions are very natural: Take for instance  $\nabla_c$ , it would be foolish to call a set  $\Phi$  of sentences “consistent under a complete calculus”, if it contains an elementary contradiction. The next condition  $\nabla_{\neg}$  says that if a set  $\Phi$  that contains a sentence  $\neg \neg \mathbf{A}$  is “consistent”, then we should be able to extend it by  $\mathbf{A}$  without losing this property; in other words, a complete calculus should be able to recognize  $\mathbf{A}$  and  $\neg \neg \mathbf{A}$  to be equivalent. We will carry out the proof here, since it gives us practice in dealing with the abstract consistency properties.

The main result here is that abstract consistency classes can be extended to compact ones. The proof is quite tedious, but relatively straightforward. It allows us to assume that all abstract consistency classes are compact in the first place (otherwise we pass to the compact extension).

Actually we are after abstract consistency classes that have an even stronger property than just being **closed under subsets**. This will allow us to carry out a limit construction in the Hintikka set extension argument later.

## Compact Collections

▷ **Definition C.1.8.** We call a **collection**  $\nabla$  of **sets compact**, iff for any **set**  $\Phi$  we have  $\Phi \in \nabla$ , iff  $\Psi \in \nabla$  for every **finite subset**  $\Psi$  of  $\Phi$ .

▷ **Lemma C.1.9.** If  $\nabla$  is **compact**, then  $\nabla$  is **closed under subsets**.

▷ *Proof:*

1. Suppose  $S \subseteq T$  and  $T \in \nabla$ .
2. Every **finite subset**  $A$  of  $S$  is a **finite subset** of  $T$ .
3. As  $\nabla$  is **compact**, we know that  $A \in \nabla$ .
4. Thus  $S \in \nabla$ .

The property of being **closed under subsets** is a “downwards-oriented” property: We go from large sets to small sets, **compactness** (the interesting direction anyways) is also an “upwards-oriented” property. We can go from small (**finite**) sets to large (**infinite**) sets. The main application for the **compactness** condition will be to show that **infinite** sets of formulae are in a **collection**  $\nabla$  by testing all their **finite subsets** (which is much simpler).

## Compact Abstract Consistency Classes

▷ **Lemma C.1.10.** *Any first-order abstract consistency class can be extended to a compact one.*

▷ *Proof:*

1. We choose  $\nabla' := \{\Phi \subseteq \text{cuff}_o(\Sigma_i) \mid \text{every finite subset of } \Phi \text{ is in } \nabla\}$ .
2. Now suppose that  $\Phi \in \nabla$ .  $\nabla$  is **closed under subsets**, so every **finite** subset of  $\Phi$  is in  $\nabla$  and thus  $\Phi \in \nabla'$ . Hence  $\nabla \subseteq \nabla'$ .
3. Let us now show that each  $\nabla$  is **compact**.
  - 3.1. Suppose  $\Phi \in \nabla'$  and  $\Psi$  is an arbitrary **finite** subset of  $\Phi$ .
  - 3.2. By definition of  $\nabla'$  all **finite** subsets of  $\Phi$  are in  $\nabla$  and therefore  $\Psi \in \nabla$ .
  - 3.3. Thus all **finite** subsets of  $\Phi$  are in  $\nabla$  whenever  $\Phi$  is in  $\nabla'$ .
  - 3.4. On the other hand, suppose all **finite** subsets of  $\Phi$  are in  $\nabla$ .
  - 3.5. Then by the definition of  $\nabla'$  the **finite** subsets of  $\Phi$  are also in  $\nabla$ , so  $\Phi \in \nabla'$ . Thus  $\nabla'$  is **compact**.
4. Note that  $\nabla'$  is **closed under subsets** by the Lemma above.
5. Next we show that if  $\nabla$  satisfies  $\nabla_*$ , then  $\nabla$  satisfies  $\nabla'_*$ .
  - 5.1. To show  $\nabla_c$ , let  $\Phi \in \nabla'$  and suppose there is an atom  $\mathbf{A}$ , such that  $\{\mathbf{A}, \neg\mathbf{A}\} \subseteq \Phi$ . Then  $\{\mathbf{A}, \neg\mathbf{A}\} \in \nabla$  contradicting  $\nabla_c$ .
  - 5.2. To show  $\nabla_{\neg}$ , let  $\Phi \in \nabla'$  and  $\neg\neg\mathbf{A} \in \Phi$ , then  $\Phi * \mathbf{A} \in \nabla'$ .
    - 5.2.1. Let  $\Psi$  be any **finite** subset of  $\Phi * \mathbf{A}$ , and  $\Theta := (\Psi \setminus \{\mathbf{A}\}) * \neg\neg\mathbf{A}$ .
    - 5.2.2.  $\Theta$  is a **finite** subset of  $\Phi$ , so  $\Theta \in \nabla$ .
    - 5.2.3. Since  $\nabla$  is an abstract consistency class and  $\neg\neg\mathbf{A} \in \Theta$ , we get  $\Theta * \mathbf{A} \in \nabla$  by  $\nabla_{\neg}$ .
    - 5.2.4. We know that  $\Psi \subseteq \Theta * \mathbf{A}$  and  $\nabla$  is closed under subsets, so  $\Psi \in \nabla$ .
    - 5.2.5. Thus every **finite** subset  $\Psi$  of  $\Phi * \mathbf{A}$  is in  $\nabla$  and therefore by definition  $\Phi * \mathbf{A} \in \nabla'$ .
  - 5.3. the other cases are analogous to  $\nabla_{\neg}$ .

Hintikka sets are sets of sentences with very strong analytic closure conditions. These are motivated as maximally consistent sets i.e. sets that already contain everything that can be consistently added to them.

## $\nabla$ -Hintikka Set

- ▷ **Definition C.1.11.** Let  $\nabla$  be an abstract consistency class, then we call a set  $\mathcal{H} \in \nabla$  a  **$\nabla$  Hintikka Set**, iff  $\mathcal{H}$  is maximal in  $\nabla$ , i.e. for all  $\mathbf{A}$  with  $\mathcal{H} * \mathbf{A} \in \nabla$  we already have  $\mathbf{A} \in \mathcal{H}$ .
- ▷ **Theorem C.1.12 (Hintikka Properties).** *Let  $\nabla$  be an abstract consistency class and  $\mathcal{H}$  be a  $\nabla$ -Hintikka set, then*

- $\mathcal{H}_c$ ) For all  $\mathbf{A} \in \text{cuff}_o(\Sigma_i, \mathcal{V}_i)$  we have  $\mathbf{A} \notin \mathcal{H}$  or  $\neg \mathbf{A} \notin \mathcal{H}$ .
- $\mathcal{H}_\neg$ ) If  $\neg \neg \mathbf{A} \in \mathcal{H}$  then  $\mathbf{A} \in \mathcal{H}$ .
- $\mathcal{H}_\wedge$ ) If  $\mathbf{A} \wedge \mathbf{B} \in \mathcal{H}$  then  $\mathbf{A}, \mathbf{B} \in \mathcal{H}$ .
- $\mathcal{H}_\vee$ ) If  $\neg(\mathbf{A} \wedge \mathbf{B}) \in \mathcal{H}$  then  $\neg \mathbf{A} \in \mathcal{H}$  or  $\neg \mathbf{B} \in \mathcal{H}$ .
- $\mathcal{H}_\forall$ ) If  $\forall X. \mathbf{A} \in \mathcal{H}$ , then  $[\mathbf{B}/X](\mathbf{A}) \in \mathcal{H}$  for each closed term  $\mathbf{B}$ .
- $\mathcal{H}_\exists$ ) If  $\neg(\forall X. \mathbf{A}) \in \mathcal{H}$  then  $\neg([\mathbf{B}/X](\mathbf{A})) \in \mathcal{H}$  for some term closed term  $\mathbf{B}$ .

▷ Proof:

We prove the properties in turn  $\mathcal{H}_c$  goes by induction on the structure of  $\mathbf{A}$

1.  $\mathbf{A}$  atomic
  - 1.1. Then  $\mathbf{A} \notin \mathcal{H}$  or  $\neg \mathbf{A} \notin \mathcal{H}$  by  $\nabla_c$ .
2.  $\mathbf{A} = \neg \mathbf{B}$ 
  - 2.1. Let us assume that  $\neg \mathbf{B} \in \mathcal{H}$  and  $\neg \neg \mathbf{B} \in \mathcal{H}$ ,
  - 2.2. then  $\mathcal{H} * \mathbf{B} \in \nabla$  by  $\nabla_\neg$ , and therefore  $\mathbf{B} \in \mathcal{H}$  by maximality.
  - 2.3. So  $\{\mathbf{B}, \neg \mathbf{B}\} \subseteq \mathcal{H}$ , which contradicts the induction hypothesis.
3.  $\mathbf{A} = \mathbf{B} \vee \mathbf{C}$  similar to the previous case
4. We prove  $\mathcal{H}_\neg$  by maximality of  $\mathcal{H}$  in  $\nabla$ .
  - 4.1. If  $\neg \neg \mathbf{A} \in \mathcal{H}$ , then  $\mathcal{H} * \mathbf{A} \in \nabla$  by  $\nabla_\neg$ .
  - 4.2. The maximality of  $\mathcal{H}$  now gives us that  $\mathbf{A} \in \mathcal{H}$ .
5. The other  $\mathcal{H}_*$  are similar

The following theorem is one of the main results in the “abstract consistency”/“model existence” method. For any abstract consistent set  $\Phi$  it allows us to construct a Hintikka set  $\mathcal{H}$  with  $\Phi \in \mathcal{H}$ .

## Extension Theorem

▷ **Theorem C.1.13.** If  $\nabla$  is an abstract consistency class and  $\Phi \in \nabla$  finite, then there is a  $\nabla$ -Hintikka set  $\mathcal{H}$  with  $\Phi \subseteq \mathcal{H}$ .

▷ Proof:

1. Wlog. assume that  $\nabla$  compact (else use compact extension)
2. Choose an enumeration  $\mathbf{A}_1, \dots$  of  $\text{cuff}_o(\Sigma_i)$  and  $c_1, \dots$  of  $\Sigma_0^{sk}$ .
3. and construct a sequence of sets  $\mathbf{H}_i$  with  $\mathbf{H}_0 := \Phi$  and

$$\mathbf{H}_{n+1} := \begin{cases} \mathbf{H}_n & \text{if } \mathbf{H}_n * \mathbf{A}_n \notin \nabla \\ \mathbf{H}_n \cup \{\mathbf{A}_n, \neg([\mathbf{c}_n/X](\mathbf{B}))\} & \text{if } \mathbf{H}_n * \mathbf{A}_n \in \nabla \text{ and } \mathbf{A}_n = \neg(\forall X. \mathbf{B}) \\ \mathbf{H}_n * \mathbf{A}_n & \text{else} \end{cases}$$

4. Note that all  $\mathbf{H}_i \in \nabla$ , choose  $\mathcal{H} := \bigcup_{i \in \mathbb{N}} \mathbf{H}_i$
5.  $\Psi \subseteq \mathcal{H}$  finite implies there is a  $j \in \mathbb{N}$  such that  $\Psi \subseteq \mathbf{H}_j$ ,
6. so  $\Psi \in \nabla$  as  $\nabla$  closed under subsets and  $\mathcal{H} \in \nabla$  as  $\nabla$  is compact.
7. Let  $\mathcal{H} * \mathbf{B} \in \nabla$ , then there is a  $j \in \mathbb{N}$  with  $\mathbf{B} = \mathbf{A}_j$ , so that  $\mathbf{B} \in \mathbf{H}_{j+1}$  and  $\mathbf{H}_{j+1} \subseteq \mathcal{H}$
8. Thus  $\mathcal{H}$  is  $\nabla$ -maximal

Note that the construction in the proof above is non-trivial in two respects. First, the limit construction for  $\mathcal{H}$  is not executed in our original abstract consistency class  $\nabla$ , but in a suitably

extended one to make it compact — the original would not have contained  $\mathcal{H}$  in general. Second, the set  $\mathcal{H}$  is not unique for  $\Phi$ , but depends on the choice of the **enumeration** of  $\text{cuff}_o(\Sigma_i)$ . If we pick a different **enumeration**, we will end up with a different  $\mathcal{H}$ . Say if  $\mathbf{A}$  and  $\neg\mathbf{A}$  are both  $\nabla$ -consistent<sup>4</sup> with  $\Phi$ , then depending on which one is first in the **enumeration**  $\mathcal{H}$ , will contain that one; with all the consequences for subsequent choices in the construction process.

## Valuations

▷ **Definition C.1.14.** A function  $\mu: \text{cuff}_o(\Sigma_i) \rightarrow \mathcal{D}_0$  is called a (first-order) **valuation**, iff

- ▷  $\mu(\neg\mathbf{A}) = \text{T}$ , iff  $\mu(\mathbf{A}) = \text{F}$
- ▷  $\mu(\mathbf{A} \wedge \mathbf{B}) = \text{T}$ , iff  $\mu(\mathbf{A}) = \text{T}$  and  $\mu(\mathbf{B}) = \text{T}$
- ▷  $\mu(\forall X.\mathbf{A}) = \text{T}$ , iff  $\mu([\mathbf{B}/X](\mathbf{A})) = \text{T}$  for all closed terms  $\mathbf{B}$ .

▷ **Lemma C.1.15.** If  $\varphi: \mathcal{V}_i \rightarrow \mathcal{U}$  is a **variable assignment**, then  $\mathcal{I}_\varphi: \text{cuff}_o(\Sigma_i) \rightarrow \mathcal{D}_0$  is a **valuation**.

▷ *Proof sketch:* Immediate from the definitions

Thus a **valuation** is a weaker notion of evaluation in **first-order logic**; the other direction is also true, even though the proof of this result is much more involved: The existence of a first-order **valuation** that makes a set of sentences true entails the existence of a **model** that **satisfies** it.<sup>5</sup>

## Valuation and Satisfiability

▷ **Lemma C.1.16.** If  $\mu: \text{cuff}_o(\Sigma_i) \rightarrow \mathcal{D}_0$  is a **valuation** and  $\Phi \subseteq \text{cuff}_o(\Sigma_i)$  with  $\mu(\Phi) = \{\text{T}\}$ , then  $\Phi$  is **satisfiable**.

▷ *Proof:* We construct a model for  $\Phi$ .

1. Let  $\mathcal{D}_i := \text{cuff}_i(\Sigma_i)$ , and
  - ▷  $\mathcal{I}(f): \mathcal{D}_i^k \rightarrow \mathcal{D}_i; \langle \mathbf{A}_1, \dots, \mathbf{A}_k \rangle \mapsto f(\mathbf{A}_1, \dots, \mathbf{A}_k)$  for  $f \in \Sigma^f$
  - ▷  $\mathcal{I}(p): \mathcal{D}_i^k \rightarrow \mathcal{D}_0; \langle \mathbf{A}_1, \dots, \mathbf{A}_k \rangle \mapsto \mu(p(\mathbf{A}_1, \dots, \mathbf{A}_k))$  for  $p \in \Sigma^p$ .
2. Then **variable assignments** into  $\mathcal{D}_i$  are **ground substitutions**.
3. We show  $\mathcal{I}_\varphi(\mathbf{A}) = \varphi(\mathbf{A})$  for  $\mathbf{A} \in \text{cuff}_i(\Sigma_i, \mathcal{V}_i)$  by induction on  $\mathbf{A}$ :
  - 3.1.  $\mathbf{A} = X$ 
    - 3.1.1. then  $\mathcal{I}_\varphi(\mathbf{A}) = \varphi(X)$  by definition.
  - 3.2.  $\mathbf{A} = f(\mathbf{A}_1, \dots, \mathbf{A}_k)$ 
    - 3.2.1. then  $\mathcal{I}_\varphi(\mathbf{A}) = \mathcal{I}(f)(\mathcal{I}_\varphi(\mathbf{A}_1), \dots, \mathcal{I}_\varphi(\mathbf{A}_k)) = \mathcal{I}(f)(\varphi(\mathbf{A}_1), \dots, \varphi(\mathbf{A}_k)) = f(\varphi(\mathbf{A}_1), \dots, \varphi(\mathbf{A}_k)) = \varphi(f(\mathbf{A}_1, \dots, \mathbf{A}_k)) = \varphi(\mathbf{A})$

We show  $\mathcal{I}_\varphi(\mathbf{A}) = \mu(\varphi(\mathbf{A}))$  for  $\mathbf{A} \in \text{cuff}_i(\Sigma_i, \mathcal{V}_i)$  by induction on  $\mathbf{A}$ .

  - 3.3.  $\mathbf{A} = p(\mathbf{A}_1, \dots, \mathbf{A}_k)$ 
    - 3.3.1. then  $\mathcal{I}_\varphi(\mathbf{A}) = \mathcal{I}(p)(\mathcal{I}_\varphi(\mathbf{A}_1), \dots, \mathcal{I}_\varphi(\mathbf{A}_k)) = \mathcal{I}(p)(\varphi(\mathbf{A}_1), \dots, \varphi(\mathbf{A}_k)) = \mu(p(\varphi(\mathbf{A}_1), \dots, \varphi(\mathbf{A}_k))) = \mu(\varphi(p(\mathbf{A}_1, \dots, \mathbf{A}_k))) = \mu(\varphi(\mathbf{A}))$
  - 3.4.  $\mathbf{A} = \neg\mathbf{B}$ 
    - 3.4.1. then  $\mathcal{I}_\varphi(\mathbf{A}) = \text{T}$ , iff  $\mathcal{I}_\varphi(\mathbf{B}) = \mu(\varphi(\mathbf{B})) = \text{F}$ , iff  $\mu(\varphi(\mathbf{A})) = \text{T}$ .
  - 3.5.  $\mathbf{A} = \mathbf{B} \wedge \mathbf{C}$ 
    - 3.5.1. similar

<sup>4</sup>EDNOTE: introduce this above

<sup>5</sup>EDNOTE: I think that we only get a semivaluation, look it up in Andrews.

- 3.6.  $\mathbf{A} = \forall X. \mathbf{B}$   
 3.6.1. then  $\mathcal{I}_\varphi(\mathbf{A}) = \top$ , iff  $\mathcal{I}_\psi(\mathbf{B}) = \mu(\psi(\mathbf{B})) = \top$ , for all  $\mathbf{C} \in \mathcal{D}_v$ , where  $\psi = \varphi, [\mathbf{C}/X]$ . This is the case, iff  $\mu(\varphi(\mathbf{A})) = \top$ .  
 4. Thus  $\mathcal{I}_\varphi(\mathbf{A})\mu(\varphi(\mathbf{A})) = \mu(\mathbf{A}) = \top$  for all  $\mathbf{A} \in \Phi$ .  
 5. Hence  $\mathcal{M} \models \mathbf{A}$  for  $\mathcal{M} := \langle \mathcal{D}_v, \mathcal{I} \rangle$ .

Now, we only have to put the pieces together to obtain the model existence theorem we are after.

## Model Existence

- ▷ **Theorem C.1.17 (Hintikka-Lemma).** *If  $\nabla$  is an abstract consistency class and  $\mathcal{H}$  a  $\nabla$ -Hintikka set, then  $\mathcal{H}$  is satisfiable.*

▷ *Proof:*

1. we define  $\mu(\mathbf{A}) := \top$ , iff  $\mathbf{A} \in \mathcal{H}$ ,
2. then  $\mu$  is a valuation by the Hintikka set properties.
3. We have  $\mu(\mathcal{H}) = \{\top\}$ , so  $\mathcal{H}$  is satisfiable.

- ▷ **Theorem C.1.18 (Model Existence).** *If  $\nabla$  is an abstract consistency class and  $\Phi \in \nabla$ , then  $\Phi$  is satisfiable.*

*Proof:*

- ▷ 1. There is a  $\nabla$ -Hintikka set  $\mathcal{H}$  with  $\Phi \subseteq \mathcal{H}$  (Extension Theorem)  
 2. We know that  $\mathcal{H}$  is satisfiable. (Hintikka-Lemma)  
 3. In particular,  $\Phi \subseteq \mathcal{H}$  is satisfiable.

## C.2 A Completeness Proof for First-Order ND

With the model existence proof we have introduced in the last section, the completeness proof for first-order natural deduction is rather simple, we only have to check that ND-consistency is an abstract consistency property.

### Consistency, Refutability and Abstract Consistency

- ▷ **Theorem C.2.1 (Non-Refutability is an Abstract Consistency Property).**  
 $\Gamma := \{\Phi \subseteq \text{cwf}_o(\Sigma_v) \mid \Phi \text{ not } \mathcal{ND}^1\text{-refutable}\}$  is an abstract consistency class.

▷ *Proof:* We check the properties of an ACC

1. If  $\Phi$  is non-refutable, then any subset is as well, so  $\Gamma$  is closed under subsets.  
*We show the abstract consistency conditions  $\nabla_*$  for  $\Phi \in \Gamma$ .*
2.  $\nabla_c$ 
  - 2.1. We have to show that  $\mathbf{A} \notin \Phi$  or  $\neg \mathbf{A} \notin \Phi$  for atomic  $\mathbf{A} \in \text{wff}_o(\Sigma_v, \mathcal{V}_v)$ .
  - 2.2. Equivalently, we show the contrapositive: If  $\{\mathbf{A}, \neg \mathbf{A}\} \subseteq \Phi$ , then  $\Phi \notin \Gamma$ .
  - 2.3. So let  $\{\mathbf{A}, \neg \mathbf{A}\} \subseteq \Phi$ , then  $\Phi$  is  $\mathcal{ND}^1$ -refutable by construction.
  - 2.4. So  $\Phi \notin \Gamma$ .
3.  $\nabla_{\neg}$ . *We show the contrapositive again*

3.1. Let  $\neg\neg\mathbf{A} \in \Phi$  and  $\Phi * \mathbf{A} \notin \Gamma$

3.2. Then we have a refutation  $\mathcal{D}$ :  $\Phi * \mathbf{A} \vdash_{\mathcal{ND}^1} F$

3.3. By prepending an application of  $\mathcal{ND}_{\neg\neg}E$  for  $\neg\neg\mathbf{A}$  to  $\mathcal{D}$ , we obtain a refutation  $\mathcal{D}$ :  $\Phi \vdash_{\mathcal{ND}^1} F'$ .

3.4. Thus  $\Phi \notin \Gamma$ .

Proof sketch: other  $\nabla_*$  similar

This directly yields two important results that we will use for the completeness analysis.

## Henkin's Theorem

▷ **Corollary C.2.2 (Henkin's Theorem).** Every  $\mathcal{ND}^1$ -consistent set of sentences has a model.

▷ *Proof:*

1. Let  $\Phi$  be a  $\mathcal{ND}^1$ -consistent set of sentences.
2. The class of sets of  $\mathcal{ND}^1$ -consistent propositions constitute an abstract consistency class.
3. Thus the model existence theorem guarantees a model for  $\Phi$ .

▷ **Corollary C.2.3 (Löwenheim&Skolem Theorem).** Satisfiable set  $\Phi$  of first-order sentences has a countable model.

*Proof sketch:* The model we constructed is countable, since the set of ground terms is.

Now, the completeness result for first-order natural deduction is just a simple argument away. We also get a compactness theorem (almost) for free: logical systems with a complete calculus are always compact.

## ▷ Completeness and Compactness

▷ **Theorem C.2.4 (Completeness Theorem for  $\mathcal{ND}^1$ ).** If  $\Phi \models \mathbf{A}$ , then  $\Phi \vdash_{\mathcal{ND}^1} \mathbf{A}$ .

▷ *Proof:* We prove the result by playing with negations.

1. If  $\mathbf{A}$  is valid in all models of  $\Phi$ , then  $\Phi * \neg\mathbf{A}$  has no model
2. Thus  $\Phi * \neg\mathbf{A}$  is inconsistent by (the contrapositive of) Henkin's Theorem.
3. So  $\Phi \vdash_{\mathcal{ND}^1} \neg\neg\mathbf{A}$  by  $\mathcal{ND}_{\neg\neg}I$  and thus  $\Phi \vdash_{\mathcal{ND}^1} \mathbf{A}$  by  $\mathcal{ND}_{\neg\neg}E$ .

▷ **Theorem C.2.5 (Compactness Theorem for first-order logic).** If  $\Phi \models \mathbf{A}$ , then there is already a finite set  $\Psi \subseteq \Phi$  with  $\Psi \models \mathbf{A}$ .

*Proof:* This is a direct consequence of the completeness theorem

- ▷ 1. We have  $\Phi \models \mathbf{A}$ , iff  $\Phi \vdash_{\mathcal{ND}^1} \mathbf{A}$ .
2. As a proof is a finite object, only a finite subset  $\Psi \subseteq \Phi$  can appear as leaves in the proof.

## C.3 Soundness and Completeness of First-Order Tableaux

The soundness of the first-order free-variable tableaux calculus can be established a simple induction over the size of the tableau.

### Soundness of $\mathcal{T}_1^f$

---

▷ **Lemma C.3.1.** *Tableau rules transform satisfiable tableaux into satisfiable ones.*

▷ *Proof:*

we examine the tableau rules in turn

1. propositional rules as in propositional tableaux
2.  $\mathcal{T}_1^f \exists$  by ??
3.  $\mathcal{T}_1^f \perp$  by ?? (substitution value lemma)
4.  $\mathcal{T}_1^f \forall$ 
  - 4.1.  $\mathcal{I}_\varphi(\forall X.\mathbf{A}) = \mathbf{T}$ , iff  $\mathcal{I}_\psi(\mathbf{A}) = \mathbf{T}$  for all  $a \in \mathcal{D}_i$
  - 4.2. so in particular for some  $a \in \mathcal{D}_i \neq \emptyset$ .

▷ **Corollary C.3.2.**  $\mathcal{T}_1^f$  is correct.

Michael Kohlhase: Artificial Intelligence 1
733
2024-02-08

The only interesting steps are the cut rule, which can be directly handled by the substitution value lemma, and the rule for the existential quantifier, which we do in a separate lemma.

### Soundness of $\mathcal{T}_1^f \exists$

---

▷ **Lemma C.3.3.**  $\mathcal{T}_1^f \exists$  transforms satisfiable tableaux into satisfiable ones.

▷ *Proof:* Let  $\mathcal{T}'$  be obtained by applying  $\mathcal{T}_1^f \exists$  to  $(\forall X.\mathbf{A})^F$  in  $\mathcal{T}$ , extending it with  $([f(X^1, \dots, X^k)/X](\mathbf{A}))^F$ , where  $W := \text{free}(\forall X.\mathbf{A}) = \{X^1, \dots, X^k\}$

1. Let  $\mathcal{T}$  be satisfiable in  $\mathcal{M} := \langle \mathcal{D}, \mathcal{I} \rangle$ , then  $\mathcal{I}_\varphi(\forall X.\mathbf{A}) = \mathbf{F}$ .  
We need to find a model  $\mathcal{M}'$  that satisfies  $\mathcal{T}'$  (find interpretation for  $f$ )
2. By definition  $\mathcal{I}_{(\varphi, [a/X])}(\mathbf{A}) = \mathbf{F}$  for some  $a \in \mathcal{D}$  (depends on  $\varphi|_W$ )
3. Let  $g: \mathcal{D}^k \rightarrow \mathcal{D}$  be defined by  $g(a_1, \dots, a_k) := a$ , if  $\varphi(X^i) = a_i$
4. choose  $\mathcal{M} = \langle \mathcal{D}, \mathcal{I}' \rangle$  with  $\mathcal{I}' := \mathcal{I}, [g/f]$ , then by subst. value lemma

$$\begin{aligned} \mathcal{I}'_\varphi([f(X^1, \dots, X^k)/X](\mathbf{A})) &= \mathcal{I}'_{(\varphi, [\mathcal{I}'_\varphi(f(X^1, \dots, X^k))/X])}(\mathbf{A}) \\ &= \mathcal{I}'_{(\varphi, [a/X])}(\mathbf{A}) = \mathbf{F} \end{aligned}$$

5. So  $([f(X^1, \dots, X^k)/X](\mathbf{A}))^F$  satisfiable in  $\mathcal{M}'$

Michael Kohlhase: Artificial Intelligence 1
734
2024-02-08

This proof is paradigmatic for soundness proofs for calculi with Skolemization. We use the axiom of choice at the meta-level to choose a **meaning** for the Skolem function symbol. Armed with the Model Existence Theorem for **first-order logic** (Theorem C.1.18), the completeness of first-order tableaux is similarly straightforward. We just have to show that the collection of tableau-irrefutable sentences is an abstract consistency class, which is a simple proof-transformation exercise in all but the **universal quantifier** case, which we postpone to its own Lemma (Theorem C.3.5).

## Completeness of $(\mathcal{T}_1^f)$

▷ **Theorem C.3.4.**  $\mathcal{T}_1^f$  is *refutation complete*.

▷ *Proof:* We show that  $\nabla := \{\Phi \mid \Phi^T \text{ has no closed Tableau}\}$  is an abstract consistency class

1. as for propositional case.
2. by the lifting lemma below
3. Let  $\mathcal{T}$  be a closed tableau for  $\neg(\forall X.\mathbf{A}) \in \Phi$  and  $\Phi^T * ([c/X](\mathbf{A}))^F \in \nabla$ .

$$\begin{array}{ccc} \Psi^T & & \Psi^T \\ (\forall X.\mathbf{A})^F & & (\forall X.\mathbf{A})^F \\ ([c/X](\mathbf{A}))^F & & ([f(X_1, \dots, X_k)/X](\mathbf{A}))^F \\ Rest & & [f(X_1, \dots, X_k)/c](Rest) \end{array}$$

So we only have to treat the case for the universal quantifier. This is what we usually call a “lifting argument”, since we have to transform (“lift”) a proof for a formula  $\theta(\mathbf{A})$  to one for  $\mathbf{A}$ . In the case of tableaux we do that by an induction on the [tableau refutation](#) for  $\theta(\mathbf{A})$  which creates a tableau-isomorphism to a [tableau refutation](#) for  $\mathbf{A}$ .

## Tableau-Lifting

▷ **Theorem C.3.5.** If  $\mathcal{T}_\theta$  is a *closed tableau* for a set  $\theta(\Phi)$  of formulae, then there is a *closed tableau*  $\mathcal{T}$  for  $\Phi$ .

▷ *Proof:* by induction over the structure of  $\mathcal{T}_\theta$  we build an isomorphic tableau  $\mathcal{T}$ , and a tableau-isomorphism  $\omega: \mathcal{T} \rightarrow \mathcal{T}_\theta$ , such that  $\omega(\mathbf{A}) = \theta(\mathbf{A})$ .

*only the tableau-substitution rule is interesting.*

1. Let  $(\theta(\mathbf{A}_i))^T$  and  $(\theta(\mathbf{B}_i))^F$  cut formulae in the branch  $\Theta_\theta^i$  of  $\mathcal{T}_\theta$
2. there is a joint unifier  $\sigma$  of  $(\theta(\mathbf{A}_1)) = ? (\theta(\mathbf{B}_1)) \wedge \dots \wedge (\theta(\mathbf{A}_n)) = ? (\theta(\mathbf{B}_n))$
3. thus  $\sigma \circ \theta$  is a unifier of  $\mathbf{A}$  and  $\mathbf{B}$
4. hence there is a most general unifier  $\rho$  of  $\mathbf{A}_1 = ? \mathbf{B}_1 \wedge \dots \wedge \mathbf{A}_n = ? \mathbf{B}_n$
5. so  $\Theta$  is closed.

Again, the “lifting lemma for tableaux” is paradigmatic for lifting lemmata for other [refutation calculi](#).

## C.4 Soundness and Completeness of First-Order Resolution

### Correctness (CNF)

▷ **Lemma C.4.1.** A set  $\Phi$  of sentences is satisfiable, iff  $CNF_1(\Phi)$  is.

▷ *Proof:* propositional rules and  $\forall$ -rule are trivial; do the  $\exists$ -rule

1. Let  $(\forall X. \mathbf{A})^F$  satisfiable in  $\mathcal{M} := \langle \mathcal{D}, \mathcal{I} \rangle$  and  $\text{free}(\mathbf{A}) = \{X^1, \dots, X^n\}$
2.  $\mathcal{I}_\varphi(\forall X. \mathbf{A}) = F$ , so there is an  $a \in \mathcal{D}$  with  $\mathcal{I}_{(\varphi, [a/X])}(\mathbf{A}) = F$  (only depends on  $\varphi|_{\text{free}(\mathbf{A})}$ )
3. let  $g: \mathcal{D}^n \rightarrow \mathcal{D}$  be defined by  $g(a_1, \dots, a_n) := a$ , iff  $\varphi(X^i) = a_i$ .
4. choose  $\mathcal{M}' := \langle \mathcal{D}, \mathcal{I}' \rangle$  with  $\mathcal{I}'(f) := g$ , then  $\mathcal{I}'_\varphi([f(X^1, \dots, X^k)/X](\mathbf{A})) = F$
5. Thus  $([f(X^1, \dots, X^k)/X](\mathbf{A}))^F$  is satisfiable in  $\mathcal{M}'$

## Resolution (Correctness)

- ▷ **Definition C.4.2.** A clause is called **satisfiable**, iff  $\mathcal{I}_\varphi(\mathbf{A}) = \alpha$  for one of its literals  $\mathbf{A}^\alpha$ .
- ▷ **Lemma C.4.3.**  $\square$  is unsatisfiable
- ▷ **Lemma C.4.4.** CNF transformations preserve satisfiability (see above)
- ▷ **Lemma C.4.5.** Resolution and factorization too!

## Completeness ( $\mathcal{R}_1$ )

- ▷ **Theorem C.4.6.**  $\mathcal{R}_1$  is refutation complete.
- ▷ *Proof:*  $\nabla := \{\Phi \mid \Phi^T \text{ has no closed tableau}\}$  is an abstract consistency class
  1. as for propositional case.
  2. by the lifting lemma below
  3. Let  $\mathcal{T}$  be a closed tableau for  $\neg(\forall X. \mathbf{A}) \in \Phi$  and  $\Phi^T * ([c/X](\mathbf{A}))^F \in \nabla$ .
  4.  $\text{CNF}_1(\Phi^T) = \text{CNF}_1(\Psi^T) \cup \text{CNF}_1([f(X_1, \dots, X_k)/X](\mathbf{A}))^F$
  5.  $([f(X_1, \dots, X_k)/c](\text{CNF}_1(\Phi^T))) * ([c/X](\mathbf{A}))^F = \text{CNF}_1(\Phi^T)$
  6. so  $\mathcal{R}_1: \text{CNF}_1(\Phi^T) \vdash_{\mathcal{D}'} \square$ , where  $\mathcal{D} = [f(X'_1, \dots, X'_k)/c](\mathcal{D})$ .

## Clause Set Isomorphism

- ▷ **Definition C.4.7.** Let  $\mathbf{B}$  and  $\mathbf{C}$  be clauses, then a **clause isomorphism**  $\omega: \mathbf{C} \rightarrow \mathbf{D}$  is a **bijection** of the literals of  $\mathbf{C}$  and  $\mathbf{D}$ , such that  $\omega(\mathbf{L})^\alpha = \mathbf{M}^\alpha$  (conserves labels)  
We call  $\omega$   **$\theta$  compatible**, iff  $\omega(\mathbf{L}^\alpha) = (\theta(\mathbf{L}))^\alpha$
- ▷ **Definition C.4.8.** Let  $\Phi$  and  $\Psi$  be clause sets, then we call a **bijection**  $\Omega: \Phi \rightarrow \Psi$  a **clause set isomorphism**, iff there is a clause isomorphism  $\omega: \mathbf{C} \rightarrow \Omega(\mathbf{C})$  for each  $\mathbf{C} \in \Phi$ .
- ▷ **Lemma C.4.9.** If  $\theta(\Phi)$  is set of formulae, then there is a  $\theta$ -compatible clause set isomorphism  $\Omega: \text{CNF}_1(\Phi) \rightarrow \text{CNF}_1(\theta(\Phi))$ .

▷ *Proof sketch:* by induction on the CNF derivation of  $CNF_1(\Phi)$ .

## Lifting for $\mathcal{R}_1$

▷ **Theorem C.4.10.** *If  $\mathcal{R}_1 : (\theta(\Phi)) \vdash_{\mathcal{D}_\theta} \square$  for a set  $\theta(\Phi)$  of formulae, then there is a  $\mathcal{R}_1$ -refutation for  $\Phi$ .*

▷ *Proof:* by induction over  $\mathcal{D}_\theta$  we construct a  $\mathcal{R}_1$ -derivation  $\mathcal{R}_1 : \Phi \vdash_{\mathcal{D}} \mathbf{C}$  and a  $\theta$ -compatible clause set isomorphism  $\Omega : \mathcal{D} \rightarrow \mathcal{D}_\theta$

$$1. \text{ If } \mathcal{D}_\theta \text{ ends in } \frac{\frac{\mathcal{D}'_\theta}{((\theta(\mathbf{A})) \vee (\theta(\mathbf{C})))^\top} \quad \frac{\mathcal{D}''_\theta}{(\theta(\mathbf{B}))^\top \vee (\theta(\mathbf{D}))}}{(\sigma(\theta(\mathbf{C}))) \vee (\sigma(\theta(\mathbf{B})))} \text{res}$$

then we have (IH) clause isomorphisms  $\omega' : \mathbf{A}^\top \vee \mathbf{C} \rightarrow (\theta(\mathbf{A}))^\top \vee (\theta(\mathbf{C}))$  and  $\omega' : \mathbf{B}^\top \vee \mathbf{D} \rightarrow (\theta(\mathbf{B}))^\top \vee (\theta(\mathbf{D}))$

$$2. \text{ thus } \frac{\mathbf{A}^\top \vee \mathbf{C} \quad \mathbf{B}^\top \vee \mathbf{D}}{(\rho(\mathbf{C})) \vee (\rho(\mathbf{B}))} \text{Res} \quad \text{where } \rho = \text{mgu}(\mathbf{A}, \mathbf{B}) \text{ (exists, as } \sigma \circ \theta \text{ unifier)}$$
