November 9, 2020

## Preface

This document contains an English glossary for the course *Informatische Werkzeuge in den Geistes- und Sozialwissenschaften* at FAU Erlangen-Nürnberg (IWGS). It is automatically generated from the sources of the IWGS course notes and should be up-to-date with the course progress.

The glossary contains definitions for all technical terms used in the course, both the ones defined in the course, as well as the ones presupposed. The latter should be relatively few, since IWGS is intended as a beginner's course.

# 1 Glossary for IWGS

**AI** **Artificial Intelligence** (AI) studies how we can make the computer do things that humans can still do better at the moment.

**ALU** Defined along with **main processor**

**Boolean** Defined along with **integer**

**CLI** A **command-line interface** (CLI) is a means of interacting with a **computer program** where the **user** (or **client**) issues **instructions** (called **commands** in a CLI) to the **program** in the form of successive lines of text (**command line**). The **program** which handles this **user interface** is called a **command-line interpreter** or **command-line processor**.

**CS** **Computer science** (or short **CS**) is the study of **algorithms** and **information processing system** in theory and practice. A **CS** professional is called a **computer scientist**.

**OS** An **operating system** (OS) is a system **program** that manages **computer hardware**, **software resources**, and provides common **services** for **computer programs**.

**RTFM** **RTFM** ( $\hat{=}$  “read those **fine** manuals”)

**RTFM** **RTFM** ( $\hat{=}$  “read the fine manuals”)

**algorithm** An **algorithm** is a formal or informal specification for solving a problem by executing a finite sequence of **instructions** (concrete or imaginary/abstract) **information processing systems**.

**argument** A **subroutine** (also called **routine** or **subprogram**) is a **program** fragment in a **program**  $P$  that performs a specific task, packaged as a unit in so that it can be executed (**called**, or **invoked**) by  $P$ .

A **subroutine**  $p$  consists of an **identifier** (its **name**), a **sequence**  $xx_1, \dots, x_n$  of local **identifiers** called **parameters**, and a **program** fragment (called the **body** of  $p$ ). The **length**  $n$  of  $x$  is called the **arity** of  $p$ .

When  $P$  (the **invoker**) **calls**  $p$ , then it supplies a list of **values** (called **arguments**) to  $p$ : the **parameters** are replaced by the **arguments**, and the **body** is executed in the context where it is **called**.  $p$  may or may not **return values**  $v$  to  $P$ , the **return values**. If it does, it is called a **function** otherwise a **procedure**.

**arity** A python **function** is defined by a code snippet of the form

```
def f (p1, ..., pn):  
    """docstring, what does this function do on parameters  
       :param pi: document arguments}  
    """  
    <<body>> # it can contain p1, ..., pn, and even f  
    return <<value>> # value of the function call (e.g text or number)  
<<more code>>
```

- the indented part is called the **body** of  $f$ , (**⚠**: **whitespace matters in python**)
- the  $p_i$  are called **parameters**, and  $n$  the **arity** of  $f$ .

A function  $f$  can be **called** on **arguments**  $a_1, \dots, a_n$  by writing the expression  $f(a_1, \dots, a_n)$ . This executes the body of  $f$  where the (formal) parameters  $p_i$  are replaced by the arguments  $a_i$ .

**assign** Defined along with **variable assignment**

- binary** Defined along with [source](#)
- body** Defined along with [loop](#)
- body** Defined along with [argument](#)
- branch** Defined along with [conditional execution](#)
- cell** [Jupyter notebooks](#) consist of [cells](#) which come in three forms
- a [raw cell](#) shows text as is
  - a [markdown cell](#) interprets the contents as markdown text (later more)
  - a [code cell](#) interprets the contents as (e.g. python) code
- class** In [object-oriented programming](#), a [class](#) is a program construct for creating [objects](#) as well as providing the [fields](#) with initial [values](#) and the [methods](#) with implementations.
- close** Defined along with [open](#)
- cloud IDE** A [web IDE](#) or [cloud IDE](#), is a browser-based [integrated development environment](#).
- code cell** Defined along with [cell](#)
- compiler** A [compiler](#) is a [program](#) that translates ([compiles](#))[code](#) written in one [programming language](#) (the [source language](#)) into another [language](#) (the [target language](#)).
- complexes** Defined along with [integer](#)
- compose** Defined along with [composition principle](#)
- composition principle** All [programming languages](#) provide [composition principles](#) that allow to [compose](#) smaller program fragments into larger ones in such a way, that the [semantics](#) of the larger is determined by the [semantics](#) of the smaller ones and that of the [composition principle](#) employed.
- putationally universal** An [information processing system](#) is said to be [Turing complete](#) or [computationally universal](#) if it can be used to simulate any [Turing machine](#).
- computer** A [computing device](#) or simply a [computer](#) is an physical (usually electrical or electronic) [information processing system](#) that can automatically [execute](#) a [sequence of machine instructions](#) i.e. arithmetic or logical operations that change [state](#) of the [system](#).  
A [computer](#) consists of physical parts (its [hardware](#)) and a set of [programs](#) and [data](#), its [software](#).
- condition** A [condition](#) is a [Boolean expression](#) in a [control structure](#).
- conditional execution** [Conditional execution](#) allows to execute (or not to execute) certain parts of a [program](#) (the [branches](#)) depending on a [condition](#). We call a code block that enables [conditional execution](#) a [conditional statement](#).
- conditional statement** Defined along with [conditional execution](#)
- control flow** The [control flow](#) of a [program](#) is the sequence of execution of the [program instructions](#). It is specified via special [program instructions](#) called [control structures](#).
- control structure** Defined along with [control flow](#)
- control unit** Defined along with [main processor](#)

**dashboard** A **dashboard** is a **user interface** that organizes and presents **system information** give an overview over the **state** of a complex **system** and its **services**.

**data** **Data** is **information** that is used to represent objects by giving values to their relevant attributes and stating their relationships.

**data language** A **data language** is a **formal language** for specifying **data** in an **information processing system**. **data languages** are not **Turing complete**.

**dot notation** Defined along with **object**

**element** Defined along with **list**

**embedded system** An **embedded system** is a **computing device** with a dedicated function within a larger mechanical or electrical **system**.

**expression** An **expression** in a **programming language** is a combination of one or more **constants**, **variables**, **operators**, and **functions** that the **programming language** computes to produce a **value**. This process is called **evaluation**.

**file** A **file** is a **resource** for recording **data** in a **storage device**.

**finite** We say that a set  $A$  is **finite** and has **cardinality** (or **size**)  $\#(A) \in \mathbb{N}$ , iff there is a **bijective** function  $f: A \rightarrow \{n \in \mathbb{N} \mid n < \#(A)\}$ .

The cardinality of a set  $A$  is also written as  $|A|$ ,  $\text{card}(A)$ ,  $n(A)$ , or  $\overline{A}$ .

**float** Defined along with **integer**

**float** A **floating point number** (or short a **float**) is a quintuple  $n := \langle \sigma, s_1, s_2, b, e \rangle$ , where

1. the **sign**  $\sigma$  is unit sequence – or the empty sequence, and the  $s_i$  are **sequence** of **digits** of **base**  $b$ . Together, (i.e. concatenated with a **decimal point** between  $s_1$  and  $s_2$ )  $\sigma$ ,  $s_1$ , and  $s_2$  make up the **significand**  $s$  (also called the **mantissa** or **coefficient**).
2. an **exponent**  $e \in \mathbb{Z}$  (also referred to as the **characteristic**, or **scale**), which modifies the magnitude of the number  $n$ .

The number  $\langle \sigma, s_1, s_2, b, e \rangle$  represents the rational number  $\frac{s}{b^{p-1}} \cdot b^e$ .

The **length**  $p := \text{len}(s_1) + \text{len}(s_2)$  of the **significand** determines the **precision** to which numbers can be represented.

**for loop** A **for loop** **iterates** a **program** fragment over a **sequence**; we call the process **iteration**. python uses the following general syntax

```
for ⟨⟨var⟩⟩ in ⟨⟨range⟩⟩:  
    ⟨⟨body⟩⟩  
⟨⟨other code⟩⟩
```

**function** Defined along with **argument**

**general-purpose computer** A **general-purpose computer** is **one** that, given the appropriate **Software** and the required time, should be able to perform arbitrary computing tasks.

**hardware** Defined along with **computer**

**input subsystem** An **information processing system** (or **information processor**) is a **stateful system** (be it electrical, mechanical or biological) which takes **information** in one form and transforms it into another form.

An **information processing system**  $S$  is made up of four **subsystems**:

1. the **input subsystem** channels **information** into  $S$ ,
2. the **processor** executes the transformation in a sequence of operations called **instructions** on the **processor state**,
3. the **storage subsystem** stores **information**, and
4. the **output subsystem** channels the transformed **information** out of  $S$ .

**instruction** Defined along with **input subsystem**

**integer** python has the following five basic **data types**

Data type	Keyword	contains	Examples
<b>integers</b>	int	bounded <b>integers</b>	1, -5, 0, ...
<b>floats</b>	float	<b>floating point numbers</b>	1.2, .125, -1.0, ...
<b>strings</b>	str	<b>strings</b>	"Hello", 'Hello', "123", 'a', ...
<b>Booleans</b>	bool	<b>truth values</b>	True, False
<b>complexess</b>	complex	<b>complex numbers</b>	2+3j,...

**integer** The set  $\mathbb{Z}$  of **integer numbers** (or **integers**) is defined as  $\mathbb{Z} := \mathbb{N} \cup \{-n \mid n \in \mathbb{N}^+\}$ .

**interpreter** An **interpreter** is a **program** that directly **executes instructions** written in a **programming language**, without requiring them previously to have been **compiled** into a machine language program.

**invoke** Defined along with **argument**

**iterate** Defined along with **for loop**

**iteration** Defined along with **for loop**

**library** A python **library** is a python file with a collection of **functions**, **classes**, and **methods**. It can be loaded via the **import** command.

**license** A **license** is an authorization (by the **licensor**) to use the licensed material (by the **licensee**).

**line** In practice, **text files** are often processed as a **sequence** of **text lines** (or just **lines**), i.e. sub-strings separated by the **line feed character** U+000A; LINE FEED (LF). The **line number** is just the position in the sequence.

**list** A **list** is a **finite sequence** of objects, its **elements**.

**list constructor** We call  $\llbracket \langle \text{seq} \rangle \rrbracket$  the **list constructor**.

**loop** A **loop** is a **control structure** that allows to execute certain parts of a **program** (the **body**) multiple times depending on **conditions**.

**main processor** A **central processing unit** (**CPU**), also called a **central processor** or **main processor**, is the electronic circuitry within a **computer** that carries out the **instructions** of a **program** by performing the basic arithmetic, logic, controlling, and input/output (I/O) operations specified by the **instructions**.

A **CPU** that consists of a

- **control unit** that interprets the **program** and controls the flow of **machine instructions** and
- a **arithmetic/logic unit (ALU)** that does the actual computations internally.

**markdown cell** Defined along with **cell**

**method** **Object-oriented programming (OOP)** is a **programming** paradigm based on the concept of an **objects**. **Objects** can contain **data**, in the form of **fields** (often known as **attribute** or **properties**) to represent **object** properties. **Object** behavior is specified via **procedures** (called **methods** in **OOP**).

**object** In python all **values** belong to a **class**, which provide special **functions** we call **methods**. **Values** are also called **objects**, to emphasise **class** aspects. **Method** application is written with **dot notation**: `«obj».«meth»(«args»)` corresponds to `«meth»(«obj»,«args»)`.

**open** Once a **file** has been **opened**, the **CPU** can **write** to it and **read** from it. After use a file should be **closed** to protect it from accidental **reads** and **writes**.

**open source** **Free/Libre/Open-Source Software (FLOSS** or just **open source**) is software that is and licensed via **licenses** that ensure that its source code is available.

**operator** An **operator** is a **function** that differs syntactically (e.g. by using infix notation) or semantically (in evaluation strategy or argument passing mode) from usual **functions**.

**output subsystem** Defined along with **input subsystem**

**pair** Let  $A$  and  $B$  be **sets**, then the **set of pairs**  $A \times B$  of  $A$  and  $B$  is defined as  $\{(a, b) \mid a \in A, b \in B\}$ , we call  $(a, b) \in A \times B$  a **pair**.  $(a, b) = (c, d)$ , iff  $a = c$  and  $b = d$ .

**parameter** Defined along with **argument**

**primary storage** The **memory** (also **primary storage**) is a **storage subsystem** in a **computer** that stores **information** for immediate use by its **CPU**.

**primitive** In a **programming language**, a **primitive** is a “basic unit of processing”, i.e. the simplest element that can be given a procedural meaning (its **semantics**) of its own.

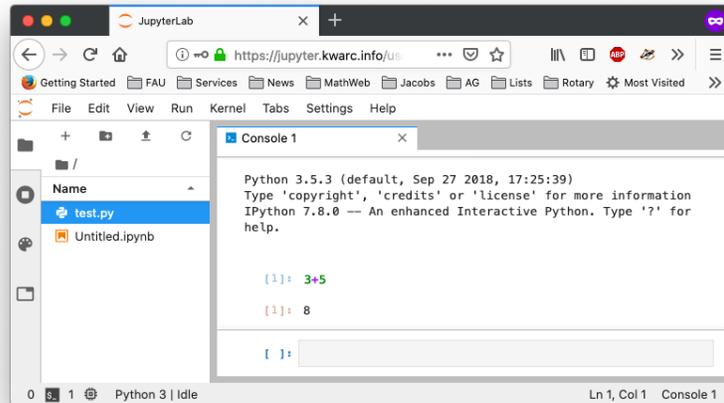

**program** A **programming language**  $L$  is a **formal language** for specifying sequences **information processing system instructions**. A **word** in  $L$  is called a **program** of  $L$ .

**programming** **Computer programming** (or just **programming**) is the process of designing and building a **program** for accomplishing a specific computing task.

It involves sub-processes, such as: analysis, generating **algorithms**, profiling **algorithms**’ resource consumption, proving **algorithm** properties, **coding**, and program verification.

**programming language** Defined along with **program**

**python console** The JupyterLab **python console**, i.e. a python **interpreter** in your **browser**. (use this for **python interaction and testing**)

**range** A **range** is a **finite sequence** of numbers it can conveniently be constructed by the `range` function: `range(⟨start⟩,⟨stop⟩,⟨step⟩)` constructs a **range** from `⟨start⟩` to `⟨stop⟩` with step size `⟨step⟩`.

**raw cell** Defined along with **cell**

**read** Defined along with **open**

**regex** A **regular expression** (also called **regex**) is a formal expression that specifies a set of strings.

**semantics** Defined along with **primitive**

**sequence** python has more **types** that behave just like **lists**, they are called **sequence types**.

**sequence** A **sequence**,  $(a_n)_{n \in S}$ , is a **function** whose domain is a **countable, totally ordered set**  $S$  (e.g.  $\mathbb{N}$ , then we often write  $(a_i)$ ). If  $S$  is **infinite**, we call any sequence  $(a_i)_{i \in S}$  on  $S$  an **infinite sequence**, and **finite sequence** otherwise. Then the **cardinality** of  $S$  is called the **length** of  $(a_i)_{i \in S}$ .

Sequences are written as

- $1, 2, 3, 4$  for a concrete finite sequence,
- $1, 2, 3, 4, \dots, 10$  for a finite sequence with ellipsis,
- $x^1, \dots, x^n$  and  $x_1, \dots, x_n$  for a sequence of upper/lower-indexed variables of length  $n$ ,
- $1, 2, 3, 4, \dots$  for an **infinite sequence**,
- $x^1, x^2, \dots$  and  $x_1, x_2, \dots$  for a sequence of upper/lower-indexed variables of length  $n$ ,

Given a sequence  $a: S \rightarrow T$ , and  $a \in S$  we write the  $i^{\text{th}}$  element of  $a$  as  $S_i$ .

**service** A **server** is a **program** or a **computer** that provides functionality – called a **service**– for other **programs** or **computers**, called **clients**.

**shell** A **shell** is a **command-line interface** for accessing the **services** of a **computer's operating system**.

**software** Defined along with **computer**

**source** **Compiler**: translates a **program** (the **source**) into another **program** (the **binary**) in a much simpler **programming language** for optimized execution on hardware directly.

**storage device** A **storage device** is any type of **hardware** that **stores** (i.e. records with the purpose of later returning) **data** in a (fixed or removable) **storage medium**.

**stream** Many operating systems use files as a primary computational metaphor, also treating other resources like **files**. This leads to an abstraction of files called **streams**, which encompass **files** as well as e.g. keyboards, printers, and the screen, which are seen as objects that can be read from (keyboards) and written to (e.g. screens). This practice allows flexible use of **programs**, e.g. re-directing a the (screen) output of a **program** to a **file** by simply changing the output **stream**.

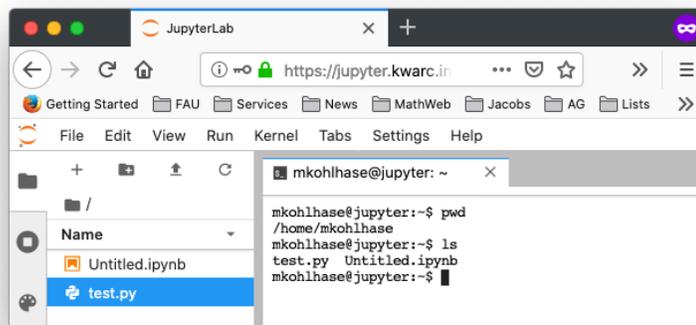

**string** Defined along with **integer**

**string** An **alphabet**  $A$  is a finite set; we call each element  $a \in A$  a **character**, and an  $n$ -tuple of  $s \in A^n$  a **word** (or **string**) of over  $A$ . We will often write a **string**  $\langle c_1, \dots, c_n \rangle$  as " $c_1 \dots c_n$ " or even as  $c_1 \dots c_n$ . We write the **empty word** (**empty string**) in  $A^0$  with  $\epsilon$ .

**symbol table** A **dictionary** (also called **associative array**, **map**, **symbol table**) is an **abstract data type** composed of a **set** of **key/value** pairs, such that each possible **key** appears at most once in the collection.

**syntax** **Programming language syntax** describes the surface form of the program: the admissible character sequences. It is also a composition of the **syntax** for the **primitives**.

**terminal** The JupyterLab **terminal**, i.e. a UNIX **shell** in your browser. (use this for managing files)

**truth value** There are two **truth values**: **true** (also called **verum**, denoted by  $T$ ,  $1$ , or  $\top$ ) and **false** (or **untrue**, also **falsum**); written as  $F$ ,  $0$ , or  $\perp$ ).

**type** A **data type** or simply **type** is an **programming language** attribute of **data** which tells the **compiler** or **interpreter** how the **programmer** intends to use the **data**.

A **type** constrains the **values** a **variable** or **function** can might take and defines the **operators** that can be applied to it.

**value** A **value** is the representation of some entity that can be manipulated by a **program**.

**variable** A **variable** is a **memory** location which contains a **value**. It is referenced by an identifier – the **variable name**.

**variable assignment** A **variable assignment**  $\langle\langle\text{var}\rangle\rangle = \langle\langle\text{val}\rangle\rangle$  assigns a **value**.

**variable name** Defined along with [variable](#)

**web browser** A [web browser](#) is a software application for retrieving (via [HTTP](#)), presenting, and traversing information resources on the [WWW](#), enabling users to view [web pages](#) and to jump from one page to another.

**write** Defined along with [open](#)
